BRIGHT, JOHN (1811-89), English politician. He was, with Richard Cobden, leader of the Anti-Corn Law League and the chief representative of the politically emerging manufacturing class. Bright had little formal schooling and entered his father's cotton manufacturing business at the age of fifteen. His interest in public questions grew out of his business experience. He became an important member of the Manchester school of economists and rose to great eminence as an orator in Parliament and on the public platform in the interests of the liberal reforms of his age.

John Bright's chief work was as headmaster of Cobden's "peripatetic political university," which aimed to align the force of public opinion behind the middle class demand for the repeal of the Corn Laws. His speeches bearing on this issue, commonly phrased in terms of ideal justice, appealed emotionally to various class and social interests. Bright himself saw the Anti-Corn Law movement as one of "the commercial and industrial classes against the lords and great proprietors of the soil," and as such it has come down in history.

Bright also supported the movement against land monopoly that was taking form in the same social situation. He argued that the land laws of England and Ireland were expressly designed to make the land a monopoly in the hands of the few and to maintain the prestige of the governing aristocracy. As late as 1870 he still blamed the landlords for the greater part of pauperism. Bright argued here, as his fundamental economic beliefs caused him to argue in other situations, for such a change in the law as would "bring the truths of political economy and the law of justice within reach of all." Specifically he urged the abolition of the law of primogeniture and entails and the establishment of freedom in the transfer of land. He also viewed as necessary the disestablishment of the church in Ireland.

In his attitude toward the labor problems of the time Bright was limited by the preconceptions of his class and by an economic creed which distrusted governmental interference in

the labor contract. He opposed factory legislation for men, although he thought there was a special case for women and children. On the other hand he was a leader in general humanitarian legislation, spoke in defense of better government of India and of religious equality and protested against the game laws, slavery and capital punishment. He was a leader in promoting parliamentary reform and political rights for working men, partly, no doubt, because working class support was necessary for further attacks by the middle class upon the privileges of the aristocracy. In 1877 Bright proudly recalled the Reform Bill of the previous decade and reminded his audience what a terrible thing it had been in prospect—"how many people said we were going to Americanize our institutions."

In international affairs Bright was a liberal, an opponent of war and a Little Englander. He looked to free trade, "the international law of the Almighty," to break down the barriers between nations. He continuously opposed the foreign policy of England and once characterized it as "neither more nor less than a gigantic system of out-door relief for the aristocracy of Great Britain."

A religious and conscientious person, a member of the Society of Friends, Bright maintained a keen interest in all those thrifty virtues which promoted the well-being of individuals. He was a model employer and kept a children's school, an adults' school and a reading room for his workers. He was interested in the temperance movement, in a cheap press and was a great admirer of the public schools of the United States. During the American Civil War, despite the widespread middle class preference for the free trade, cotton growing South, Bright urged the importance of a Union victory for the further progress of democracy in England. Appealing to religious and moral rather than economic considerations Bright threw his weight with the North and did much to restrain English intervention.

BRINKERHOFF, ROELIFF (1828-1911), one of the outstanding figures in social service in the United States during the last quarter of the nineteenth century. As an active politician he had swung from the Democratic party to the Republican on the slave issue and back again on free trade. In 1873 he established a savings bank, retired from his other activities and devoted the rest of his active life to banking and to the still later interest of social service, particularly of penology. All of his life he rode hobbies—well and thoroughly. Social service “for the love of God and humanity,” as he was wont to express it, was his last and greatest hobby. In 1878 he was appointed to the Ohio Board of State Charities and remained a member until his death. He succeeded ex-President Hayes as president of the National Prison Association and was vice president of the International Prison Congress which met in Paris in 1895. General Brinkerhoff was a prolific writer and speaker for prison reform and for reformed methods of care of state wards in general. The proceedings of the National Conference of Social Work and of the American Prison Association for a period of more than twenty years are eloquent of his interest. His *Recollections of a Lifetime* (Cincinnati 1900) tells the story of a versatile and active career. He was one of a hardy group of pioneers in the pre-professional days of social work and enriched the social service of his time by wide experience, mature judgment and boundless energy.

JOSEPH P. BYERS

Consult: National Conference of Charities and Corrections, *Proceedings*, vol. xxxviii (1911) 478-79.

BRINTON, DANIEL GARRISON (1837-99), American anthropologist. After preparing for the practise of medicine Brinton rendered distinguished service as a surgeon in the Civil War. His interest in medicine continued and in 1874 he became editor of the *Medical and Surgical Reporter*, which rose under his hand to a place of leadership in medical science. In 1887, however, he retired to devote himself to anthropology.

Even at the beginning of his medical career the anthropology of the New World had been a rival interest; it became the field which ultimately claimed his entire attention. To it he devoted years of teaching, and from the publica-

tion of his first book, *Notes on the Floridian Peninsula* (Philadelphia 1859), to his death he contributed a series of writings totaling twenty-three books and more than two hundred articles. Brinton was one of the early academic figures in American anthropology, being appointed in 1886 to a professorship in linguistics and archaeology at the University of Pennsylvania, the second American university to create a chair in anthropology. He was, with Gallatin and Morgan, one of the founders of the ethnological study of the American Indians. In the field of linguistics he showed a remarkable ability for mastering and classifying Indian languages and displayed considerable polemic power in contesting the theory of the Asiatic origin of American Indian civilizations. He sought to prove, on the basis of monographic studies of peculiar morphological traits, that the American Indian languages constituted one of the great speech families of the world. His *The American Race: a Linguistic Classification and Ethnographic Description of the Native Tribes of North and South America* (New York 1891) was a pioneer work.

But Brinton's most important contribution lay in the field of religion and mythology. He diligently collected and translated aboriginal materials for the *Library of Aboriginal American Literature* (1882-87), which provided the native text of Indian mythology and folklore with translation and notes by the editors. Brinton himself edited most of the volumes in this series, among them a publication of the first importance, *The Maya Chronicles*. In addition to this gathering of source materials Brinton carried through analyses and synthetic interpretations, starting with *The Myths of the New World: a Treatise on the Symbolism and Mythology of the Red Race in America* (New York 1868) and ending with his *Religions of Primitive People* (New York 1897). The postulate of the psychic unity of mankind underlies all his work in the field of comparative religion and caused him to argue for the spontaneous origin of religious parallelisms.

Brinton's work was almost entirely based on research rather than field work. He was, however, exacting in method and dynamic in treatment. Abroad as well as at home he was recognized as the leading American anthropologist of his generation.

CLARK WISSLER

Consult: “The Brinton Memorial Meeting” in American Philosophical Society, *Proceedings*, memorial vol. (1900) 210-72, which contains a complete

bibliography of Brinton's writings; Chamberlain, H. F., in *Journal of American Folk-Lore*, vol. xii (1898): 215-25; Boas, F., in *Globus*, vol. lxxvi (1899) 165-66.

BRINZ, ALOIS VON (1820-87), German jurist. Brinz was professor of law at Erlangen, Prague, Tübingen and Munich. Beginning with classical philology, he soon turned to jurisprudence. He intended at first to study Roman law sources only by way of preparation for later Germanistic studies but they attracted him to such an extent that he remained a Romanist. In this field he wrote his most important work, the *Lehrbuch der Pandekten* (2 vols., Erlangen 1857-71; 2nd ed., 4 vols., 1873-92). He is known particularly for his theory of juristic persons, regarding them as fictitious and existing only for the furtherance of definite objects. His doctrine of debt and liability appeared in modified form in Amira's work (disapproved, however, by Brinz himself); it was acclaimed in the Germanistic school and then surprisingly was also accepted by investigators of ancient law. Today it is recognized as fundamental. Brinz also has to his credit numerous dogmatic and historical essays such as his studies of *obligatio* and *compensatio*. His positivist, critical contributions to the *Kritische Vierteljahrsschrift für Gesetzgebung und Rechtswissenschaft* founded the reputation of that journal. His celebrated review of Ihering's doctrine of juristic construction is particularly worth reading in the present period of disputes over method.

During his sojourn at Prague (1857-66) Brinz was also active politically. Although of Austrian origin and sympathies he worked for a united Germany.

FRANZ SOMMER

Consult: Lotmar, P., in *Allgemeine deutsche Biographie*, vol. xlvii (1903) 241-59; Stintzing, R. von, and Landsberg, E., *Geschichte der deutschen Rechtswissenschaft*, 3 vols. (Munich 1880-1910) vol. iii, pt. 2, p. 842-47.

BRISBANE, ALBERT (1809-90), American social theorist. Of wealthy parentage, Brisbane as a young man traveled widely through Europe and Asiatic Turkey, observing social institutions and establishing intimate personal contacts with contemporary intellectual and social movements. He met Fourier, became his ardent disciple and upon his return to America in 1834 began a most successful campaign to disseminate Fourier's ideas. Brisbane's *Social Destiny of Man* (Philadelphia 1840) impressed Horace Greeley, who joined him in founding and editing

Fourierist journals and finally turned over to him a column in the New York *Tribune* (1842-44) to be devoted to the cause. Brisbane was the leading spirit in the establishment of several phalanxes, notably the North American Phalanx (1842), and succeeded in converting many of the Brook Farm group to the idea. Although the failure of most of these experiments in the fifties led to the cessation of Brisbane's active participation in the movement, he did not admit the failure of the underlying principles, which he restated in his *General Introduction to Social Science* (New York 1876). The remainder of his life was devoted largely to the invention of several mechanical devices.

Brisbane has been called the first American socialist. Nevertheless he despised political action, refusing to see any essential distinction between the American republic and the despotism of the sultan of Turkey, and considered the class struggle futile and destructive. He was no exponent of a new system of ethics, justice or human rights, but subordinated all these to the "efficiency" principle, which he opposed to the principle of competition. In Brisbane's plan as in Fourier's, the capitalist would continue to share in the returns because of his ownership of the capital; but production would be so much increased that the three twelfths given to the capitalist would not be missed by the workers. This staggering increase in economic productivity would be brought about by an organization of both production and consumption under a cooperative phalanstery.

SELIG PERLMAN

Consult: Brisbane, Albert, *A Mental Biography* (Boston 1893); Ware, Norman, *The Industrial Worker, 1840-60* (Boston 1924) p. 164-74; Commons, J. R., and associates, *History of Labour in the United States*, 2 vols. (New York 1918) vol. i, p. 497-506.

BRISSAUD, JEAN BAPTISTE (1854-1904), French social and legal historian. Brissaud held professorships on the law faculties of Berne, Montpellier and Toulouse. He translated into French several volumes of Mommsen and Marquardt's manual of Roman antiquities, was from 1880 until his death an editor of the *Revue générale du droit* (Paris) and a frequent contributor to other scientific journals. He compiled important bibliographies of the customs of southern France, published in the *Kritischer Jahresbericht über die Fortschritte der romanischen Philologie* (vol. v, pt. iii, 1898, p. 60-76).

Brissaud's study of the work of Claude Joly constitutes an important contribution to the

history of the casuist school of international law. His *Manuel d'histoire du droit français* (2 vols., Paris 1898-1904, 2nd ed. 1908; pts. ii and iii tr. in vols. ix and iii of *Continental Legal History* series, Boston 1915 and 1912) is Brissaud's most extensive treatise. Critical and erudite, it recalls in method and value the German *Lehrbücher*, especially the work of Richard Schroeder. Brissaud combines the comparative and the historical methods in this study of French law. His treatment is not formal but organic; he seeks the economic, social and political causes of legal growth and tries to portray the environment in which constitutional institutions developed. In showing the evolution of French law from Roman down to modern times he makes constant use of foreign sources. The four hundred pages of source material in the work constitute a complete documentary exposition of ancient law.

JOSEPH DELPECH

Consult: Roschach, E., in *Académie des Sciences, Inscriptions et Belles-Lettres de Toulouse, Mémoires*, 10th ser., vol. v (1905) 315-48, including a bibliography of Brissaud's works; Caillemier, R., and Delpech, J., in *Revue du droit public et de la science politique*, vol. xxii (1905) 454-60.

BRISSET DE WARVILLE, JACQUES-PIERRE (1754-93), French journalist, social reformer and revolutionary leader. He was educated at Chartres and at fifteen began to study law but soon abandoned it. His great humanitarian zeal found a ready outlet in journalism, which he aimed to make a medium of enlightenment and social reform. His interest in the abolition of slavery led him to organize in 1788 the *Société des Amis des Noirs*, which under Brissot's direction later exercised a considerable influence on revolutionary colonial policy. He also gave momentum to the penal reform movement. In *Recherches philosophiques sur le droit de propriété et de vol* (Chartres 1780) he based his argument against the death penalty for larceny on the principle that the institution of property in modern society is a violation of natural law. It was in this work that the phrase later made by Proudhon, "La propriété, c'est le vol," first appeared. Fundamentally, however, Brissot believed in the protection of property and went no farther in his social program than to demand work for all.

Brissot evinced a strong interest in the United States and both through the Gallo-American Society, which he founded, and through his *De*

la France et des États-Unis (London 1787, new ed. Paris 1791; tr. into English as *Considerations on the Relative Situation of France and the United States*, London 1788, and as *Commerce of America with Europe*, London 1794), in which he collaborated with Clavière, he advocated the fostering of commercial relations between France and America. After traveling in the United States on behalf of a group of French financiers to gather information for speculation in the American debt and western lands he wrote his well known *Nouveau voyage dans les États-Unis de l'Amérique septentrionale, fait en 1788* (published with *De la France et des États-Unis*, 3 vols., Paris 1791; tr. into English, 2 vols., 2nd ed. London 1794), in which he expressed his admiration for the simplicity of American life. The enthusiasm he thus displayed was thought by his political opponents during the revolution to add weight to their grave charge that Brissot desired to model the French constitution on the American.

Shortly after the revolution began Brissot launched a daily newspaper, *Le patriote français*, which was to become the chief organ of the Girondists. He soon made his influence felt in revolutionary circles; and in the Legislative Assembly and later in the Convention he became one of the recognized leaders of the Girondists, who were also called Brissotins. He was particularly influential in the precipitation of the foreign wars, through which he hoped that revolutionary doctrine would be disseminated. After the victory of the Mountain in May, 1793, Brissot was proscribed with the other leaders of his party and on October 31 he mounted the scaffold.

ELLIOTT M. GRANT

Consult: Brissot's *Mémoires*, containing critical essay and notes, ed. by Cl. Perroud, 2 vols. (Paris 1911); Ellery, Elorse, *Brissot de Warville, a Study in the History of the French Revolution* (New York 1915); Davis, J. S., *Essays in the Earlier History of American Corporations*, 2 vols. A., *La politique extérieure de Brissot et des girondins* (Paris 1912); Lichtenberger, André, *Le socialisme au XVIII^e siècle* (Paris 1895) p. 413-19.

BROADHURST, HENRY (1840-1911), English trade union leader and Liberal-Labor politician. After achieving prominence as an officer of the conservative and powerful stonemasons' union he was in 1875 appointed secretary of the

Parliamentary Committee of the Trades Union Congress. By 1875 trade unionism had won its severest parliamentary battles so that except for the important Employers' Liability Act, the passage of which Broadhurst greatly facilitated, his program was limited to minor, though useful, reforms. Both in his middle class philosophy and in his emphasis upon legislation as a means of raising the status of trade unions Broadhurst continued the tradition established by Applegarth and other members of the "Junta." In 1880 he entered the House of Commons as a Liberal and rendered such service to his party that in 1885 he was named under-secretary of state to the Home Department, the first working class appointment to the ministry. Thus his career exemplifies the alliance of labor with liberalism under Gladstone. Broadhurst's influence within the unions began to wane about 1885 with the rise of a new school of thought which had grown out of socialist doctrines and changed economic conditions. Against the demands of these new leaders for independent political action and a legal eight-hour day Broadhurst continued to defend the traditional policy. Although within the limits of his program he showed great skill and industry his policy was condemned by the Trades Union Congress and in 1890 he resigned from the secretaryship. He remained in Parliament until 1906 as a member of the radical wing of the Liberal party.

FRANCES E. GILLESPIE

Consult: Broadhurst's autobiography, *Henry Broadhurst, M. P.: The Story of his life from a Stonemason's Bench to the Treasury Bench* (2nd ed. London 1901), Davis, W. J., *The British Trades Union Congress* (London 1910); Webb, S. and B., *The History of Trade-Unionism* (rev. ed. London 1920).

BROCA, PIERRE-PAUL (1824-80), French anthropologist. After studying medicine and specializing in anatomy Broca became lecturer at the University of Paris and in 1867 professor of anatomy. His interest in comparative anatomy was focused by the contemporary controversy, stirred up by Darwin's writings, as to the monogenetic or polygenetic origin of man. Refusing to compromise as did those who attempted to soften their scientific position as to man's relationship to the apes, Broca showed that the anthropoids are to be regarded not as quadrupeds but as bipeds and thus closely identified with man. His later detailed studies on the brain bore out his position. From 1861 to 1865 he specialized in research in the localization of

function in the brain, and marked the place of speech control as resting in the third frontal convolution, which has been named the "convolution of Broca."

Broca was always interested, however, in the larger aspects of the study of the human form and was ever alive to the importance of the recognition of its close relationship to the study of human culture. He founded in 1859 the Société d'Anthropologie and after attaining his professorship he started the Institut d'Anthropologie. Here in the laboratory he inaugurated research on the comparative anatomy of primates and also gave large consideration to the task of perfecting instruments which would enable more accurate anthropometric and craniometric measurements to be made. His *Instructions générales pour les recherches anthropologiques à faire sur les vivants* (Paris 1865, 2nd ed. 1879) and his *Instructions craniologiques et craniométriques* (Paris 1875) did much to crystallize anthropometric method at a crucial time. After the war of 1870, in which he served as physician, he founded the *Revue d'anthropologie* in January, 1872, and remained its editor until his death. In 1876 he founded the École d'Anthropologie, which was finally combined with the anthropological society and laboratory to form the Institut Anthropologique. In later years Broca gave much attention to the problem of cerebral morphology.

MELVILLE J. HERSKOVITS

Important works: Broca's more important anthropological writings were collected as *Mémoires d'anthropologie*, 5 vols. (Paris 1871-88).

W., in *Journal of the Anthropological Institute*, vol. x (1881) 242-61.

BROCKWAY, ZEBULON REED (1827-1920), American penologist. After several years of service as a prison official he became in 1861 head of the House of Correction in Detroit. Brockway was the first to incorporate the indeterminate sentence in American statutes. In 1869 he drafted a Michigan law embodying this principle but it was soon practically nullified by the courts. Of far greater importance in this connection was Brockway's drafting of legislation concerning the treatment of inmates at the recently opened New York State Reformatory at Elmira and directing that male first offenders between sixteen and thirty be sent to that institu-

tion under an indeterminate sentence. As a reluctant concession to the courts and the public Brockway incorporated in this legislation the provision that the term should not exceed the maximum specified by law for the crime committed. The success which Brockway's experiment was to meet has been partly responsible for the fact that today most states have indeterminate sentence laws applying to varying numbers of persons committed to reformatories and prisons.

Elmira was the first state reformatory for male adults in the United States. As its first superintendent (1876-1900) Brockway put into effect the provisions specified in the law—a system of marks and classifications as an incentive to good behavior, parole and the indeterminate sentence—and further elaborated his program of reform by introducing physical and military training, general education and trade instruction. Brockway's methods, known as the "Elmira system," have attracted attention in many countries. Elmira remains one of the most progressive reformatories in the United States.

BROGGIA, CARLO ANTONIO (1683-1763), Italian merchant and writer on public finance. At Naples he came under the influence of Bartolomeo Intieri and Marchese Rinuccini who, according to Galiani, interested him in economic study. His principal achievement was to outline with far more insight than the cameralists and his other contemporaries a system of taxation. As described in the *Trattato dei tributi; delle monete e del governo politico della sanità* (Naples 1743; reprinted with his other works in the Custodi collection, first part, vols. iv and v, Milan 1804) this plan combined direct and indirect taxation with a view to distributing the burden in proportion to ability to pay. Direct taxes were to be not personal but impersonal, and were to be levied against fixed returns from land and capital, not excluding loans to the state or community. Industrial profits and personal property were to be reached indirectly by means of import and export duties, sufficiently low not to restrict trade, and by other types of consumption taxes. Broggia also insisted

upon greater simplicity and less arbitrariness in the assessment and collection of taxes. He was exiled to Palermo as a result of a later pamphlet, *Memoria ad oggetto di varie politiche ed economiche ragioni* (Naples 1754), in which he criticized the Neapolitan ministry and maintained, against the jurists of the old school, the right of the state to redeem tax farm concessions granted its creditors, at any time and at the current price.

BROGLIE, ACHILLE VICTOR, Duc DE (1785-1870), French statesman and diplomat, son of Prince Victor Claude Broglie. His education in the republican schools after the Terror and the influence of Mme. de Staël and other liberal aristocrats made him deeply devoted to "new France." Entering public life at an early age he served Napoleon as auditor in the Council of State and as attaché on various diplomatic missions. Under the Restoration he voted with the governmental opposition in the Chamber of Peers and used his influence somewhat unsuccessfully to liberalize the policy of the Bourbons. When the July Monarchy was established Broglie, who had been acting in concert with the *doctrinaires* since 1827, joined the government: in 1832 he was made minister of foreign affairs and in 1835 leader of the ministry. His attitude toward the Mehmet Ali affair, the Carlist revolt in Spain and other international crises was dominated by the desire to preserve the friendship of England, already won by Talleyrand, and if possible to thwart Russia. Convinced that Louis Philippe guaranteed to the French nation an important place in foreign affairs as well as a certain measure of internal freedom, Broglie vigorously opposed the efforts of republicans to overthrow the regime and sponsored the laws of 1835 aimed at judicial repression and intimidation of the press. His powerful influence, radiating through his wife's salon, helped to create the illusion that the July Monarchy was destined to remain. During these years he also directed his influence against the slave trade and was responsible for the measure of 1845 providing for the gradual abolition of slaves in French colonies. When the Revolution of 1848 came he made a fruitless effort in the National Assembly to restore the constitutional monarchy. For the rest of his life he pursued in

retirement a policy of bitter opposition to the Second Empire.

BROKER. A broker is an intermediary who negotiates a sales contract between two parties. Although the broker is in some ways similar to an agent and to a commission merchant or factor, at law he is clearly distinguished from both. The agent, while acting within the scope of his general authority, may bind his principal; the commission merchant who is actually possessed of his principal's goods may make a sale which is binding upon his principal; but the broker acts only in individual transactions, has no general authority and discloses the names of the principals, who confirm the arrangements.

When acting strictly within a broker's capacity he is the most highly specialized of middlemen. The broker carries no stock, takes no market risks, finances no operation, transfers no title. He assumes such functions only if he becomes something more than a broker. His commission is earned when a contract to sell is made, whether or not the contract is satisfactorily executed.

In actual practice the activities of brokers, commission men, sales agents and even merchants at times shade into one another to such an extent that they become almost indistinguishable. The United States census of 1920 lists the following classes and numbers of "brokers": bankers and bank officials, 82,375; commercial brokers and commission men, 27,552; loan brokers, loan company officials and pawnbrokers, 5,473; stock brokers, 29,609; promoters and brokers not specified, 16,604. This list includes many who are brokers in name rather than in fact.

The broker is most important in establishing trade connections in industries of large volume made up of many producers competing for a wide market, such as soft coal, fresh fruit and vegetables, and grain. In such industries a corps of alert brokers located in strategic cities, aware

of one another and actively in touch with trade needs in their localities, may perform without organization almost all the functions of the highly organized exchanges. Their intercommunication plays an important part in determining prices, routing goods and guiding production.

The broker is also significant in negotiating trades in property rights that do not directly affect production. Such activity is well illustrated by the stock broker and the real estate broker. Although not usually described as a broker the employment agent should properly be so classed, as it is he who brings together those who have labor to sell and those who wish to buy it.

Classed as they are designated in business, the following types of brokers are important: merchandise brokers, insurance brokers, real estate brokers, ship brokers, bill brokers, stock brokers. The merchandise broker is as a rule concerned with arranging sales between manufacturers and wholesalers and between producers and users of raw material, although he sometimes brings manufacturers together or creates contacts with retailers. The employment of brokers as a substitute for a sales force is a particular economy to small concerns.

Insurance brokers bring together the agents of insurance companies and those who desire insurance. The insurance broker best serves those in need of several types of protection and those whose risks are so large that they must be divided.

A real estate broker consummates both sales and leases, handling farms, domestic dwellings and commercial and factory property. With real estate brokerage he commonly combines brokerage in insurance for his clients and in money to meet the needs of purchasers.

The functions of the broker in organizing trade relationships are nowhere better illustrated than in the work of ship brokers, whose task it is to keep informed of the movements of vessels, the cargo space available and the rates for shipment and, in turn, to apprise prospective shippers of opportunities for shipping. As the so-called "lines" have their own agents for this work, the ship broker serves chiefly the tramp carriers. In addition to his other services he sometimes serves as port agent, settling the bills for stores and supplies, pays the crew's wages and secures insurance for vessel and cargo. Ship brokers also negotiate sales of ships.

In the organized markets, such as the grain and stock exchanges, the broker has various

forms of activity. In the larger organized markets the volume of brokerage business, in the strict sense of the term, is small, and the greater part of the transactions consists of commission or straight merchandising. It is at points where there is no active exchange and in trade between cities, however, that the grain broker is most profitably active. In arranging shipments between markets the grain broker acts as other merchandise brokers do. Working at the request of either buyer or seller, he asks for offers or bids from brokers or buyers in other cities. These offers are confirmed if satisfactory and the broker receives his commission from his original correspondent.

Members of organized stock exchanges are often indiscriminately referred to as brokers, although most of them do no brokerage business. Aside from members who trade on their own account, the bulk of the business is carried on by members who function as commission merchants, take full responsibility for the execution of trades and do not report the names of their principals. There is, however, a group of members, known in the New York Stock Exchange as "two-dollar brokers," who conduct actual brokerage transactions. These men do the active floor work for representatives of commission houses, taking no responsibility for the solicitation of business, the delivery of stock, payment or collections.

In the money market there is very little brokerage. In England the term "bill broker," which served as a fairly accurate designation in the first half of the nineteenth century, is now loosely applied to dealers who buy and sell notes and acceptances and are more properly called discount houses. In America the term "note broker" is sometimes applied to dealers who buy promissory notes from business men and sell them to banks; this business is properly known at present as that of the commercial paper house, while traders in acceptances and foreign bills are known in America as acceptance dealers.

Among those frequently misnamed "brokers" there are also the customs broker and the pawnbroker. The former is an agent acting for importers in estimating duties and in clearing goods, rather than a broker, while the latter is a sort of private money lender.

BROKERS' LOANS, as the term is popularly understood, are the borrowings made by members of the New York Stock Exchange to enable them to carry securities purchased for their customers on margin; the term applies of course to similar borrowings by members of other stock exchanges in the United States. When a broker's customers buy stocks without paying for them in full the title to these securities remains with the broker. He must pay for them, however, immediately upon delivery. Since he seldom has sufficient capital to pay the difference between the customer's margin and the cost of the securities he is forced to borrow a portion of this difference. He does this by turning over to a bank, or to some other lender, an amount of securities sufficient to guarantee the necessary loan. The securities deposited with the lender are commonly known as collateral; and the loan secured by them is called a broker's loan.

Such loans are either time loans, which may run for thirty, sixty or ninety days, or demand loans, popularly known as "call loans." Usually call loans exceed the amount of time loans, but the relation of the totals of these two categories varies widely from time to time. Although the statistics for brokers' loans in New York City are available only for the period beginning with the year 1926, they disclose a considerable range of fluctuation. Thus on September 30, 1929, which marks the highest point attained by brokers' loans, more than 91 percent was represented by demand loans, while at the end of March, 1926, demand loans amounted to only 67 percent of the total. The broker naturally chooses the form of loan and the duration which in his judgment provide the funds at the lowest cost. When rates on time money are very high, as they were in the autumn of 1929, a broker may borrow on demand, even though call rates are higher than time rates. If he expects the stringency to be of short duration the broker prefers to pay the high call rate for a few weeks

rather than to borrow money on a time loan extending over a period of ninety days.

Funds for brokers' loans are supplied by banks in the city of New York, banks in the United States outside of New York and foreign banking institutions. In addition a very large portion of these loans is supplied by corporations and individuals with surplus funds who find the rates and the conditions under which they may demand repayment attractive. These surplus funds are not bank credit but moneys which their owners might otherwise have invested in stocks and bonds did they not consider it more advantageous at the time to lend them to others for investment purposes.

It is impossible to ascertain the exact proportion of brokers' loans made by banks as distinguished from other lenders. Statistics regarding brokers' loans in New York are compiled by two independent agencies. The New York Stock Exchange has published since January, 1926, monthly statements showing its members' net borrowings on collateral as of the close of the month. Although these statements give separate figures for borrowings from New York banks or trust companies and from other sources they furnish no clue to the amount of funds which were loaned by banks out of their own resources, since the banks also act as agents for others in making these loans. Beginning with the early part of 1926 the Federal Reserve Board in Washington has published weekly statements of total loans granted to brokers and dealers on security of stocks and bonds by member banks in New York City. These statements appear on Friday morning and show the figures as of the close of business on Wednesday. They classify loans by New York member banks into three groups: those made for their own account, for account of out of town banks and for account of others. The statement as of April 2, 1930, reports a total of \$3,968,000,000 in brokers' loans, \$2,651,000,000 of which was for account of New York and out of town banks. This figure may be taken as fairly representative of the amount of credit extended to brokers by banks in the United States. It is true that the amounts loaned for out of town banks include some small sums furnished by the customers of those banks; but these are probably offset by a few loans made by domestic banks which are not members of the reserve system, not through New York banks as agents, but directly to brokers. Of the total amount borrowed by brokers at the end of March, 1930, (\$4,656,302,339 as reported by

the New York Stock Exchange for March 31, 1930), only 57 percent, therefore, was furnished by domestic banks. The remainder was loaned by individuals, corporations and foreign banking institutions.

It should be observed in passing that loans to brokers do not represent all the credit which banks extend to borrowers on stocks and bonds as collateral. The quarterly reports which the member banks make to the Federal Reserve Board show that their security loans amount at present to almost ten billion dollars. This figure includes loans to brokers. During the three years for which statistics are available loans to brokers amounted to between 25 and 30 percent of the total loans on securities made by members of the Federal Reserve system. They constitute on the average about 10 percent of the total loans of these banks and 8 percent of their total loans and investments.

During the last few years the subject of stock exchange borrowings has been given unusual prominence in financial discussion. This is largely due to the facts that on January 30, 1926, the loans were found to total about 3513 million dollars, which was 1000 million in excess of the private estimates that had previously been current, and that after declining to about 2767 million at the end of May, 1926, these loans began a renewed rise which continued with minor interruptions until they reached a maximum figure of approximately 8549 million on September 30, 1929. This rise in brokers' loans brought forth several lines of criticism. The first of these was that the expansion was producing a dangerous inflation of bank credit. The second was that the expansion of loans to the stock exchange represented a diversion of credit from industry. It was also charged that the flow of credit into the security markets was unduly large and was fostering a speculative mania which was driving the prices of stocks to unwarranted heights.

These criticisms raised some fundamental questions as to the effect of brokers' loans upon the credit structure and upon interest rates. The assertion that the expansion of these loans brought about an equal expansion of bank credit did not take into account the fact that almost the entire increase in brokers' loans consisted not of bank loans but of loans by other creditors. At the end of January, 1926, when the figures were first reported, 2488 million dollars represented loans by domestic banks, while slightly over 1000 million came from the others. By May of

the same year, when the low point was reached, bank loans totaled 1905 million dollars and other loans 862 million. When the maximum was reached at the end of September, 1929, bank loans stood at 2897 million while other loans amounted to 5652 million. The increase from the beginning of the publication of these statistics to the maximum point may be attributed almost entirely to these other loans.

It is clear that the loans by other creditors in no wise expanded the bank credit outstanding in this country and that they did not, therefore, contribute to any credit strain during the period when brokers' loans were rising. The funds which are loaned by individuals and corporations consist either of savings which they have on deposit at a bank or of money which they have received for the sale of securities through a broker. In the former case the capitalists are merely lending credit already outstanding in the form of bank deposits, which is quite different from direct lending by banks. While every bank loan creates a deposit and while an increase in the total loans made by all banks must of necessity increase the total bank deposits and consequently the total credit outstanding, a depositor's loan to a broker or to anyone else creates no new deposit; there is merely a transfer of a deposit which was already in existence. In the second case, when the individuals and corporations are not lending deposits already in existence but are placing with the broker funds which they have received by selling stocks or bonds through some brokerage house, the transaction is in no way related to bank credit since neither bank loan nor bank deposit is involved.

An argument which occurred even more persistently was the assertion that the increase in brokers' loans constituted a diversion of credit from industry and thus caused an increase in the cost of capital for legitimate business purposes. It would be unprofitable to discuss at this point the question whether it is proper to employ bank credit in order to purchase industrial securities and thus to finance the long time needs of industry. This question bears on the total amount of security loans made by banks; of these brokers' loans comprise, as has been shown above, only one fourth. With reference to the diversion of credit from industry it can be demonstrated that practically all of the additional bank credit created through brokers' loans by banks went ultimately to purchase securities from some corporation. Brokers do not borrow money in order to carry deposit balances at the

bank or to get currency for payrolls; they borrow because their customers have purchased securities from someone. If they have purchased these from corporations which issued rights to their stockholders to subscribe for new stock then clearly the proceeds of brokers' loans are paid to the corporations which gave the rights, and the credit created by the loan stands as a deposit in the name of that company. This credit has flowed into industry, but it was borrowed by the stockholders rather than by the corporation directly. If the funds derived from brokers' loans are used to purchase securities from previous owners these owners will in turn buy other securities sooner or later. Ultimately the funds will be expended for the purchase of stocks and bonds from some corporation which has issued them and which needs the credit for its industry. This does not prejudice the question as to the efficiency of financing industry by such indirect methods. While they reach industry ultimately these funds probably do not in their entirety reach the particular branches of industry the securities of which were purchased with the aid of brokers' loans. Some part of the funds remains in the hands of speculators, who invest it directly, or indirectly through increased consumption, in industries other than those on the securities of which they may have realized handsome profits.

One of the reasons why brokers' loans have increased so rapidly in recent years is that they had shrunk to an abnormally low volume during the war and the post-war depression. Statistics compiled for confidential use by the New York Stock Exchange for the period October, 1918, to December, 1922, (published in New York Stock Exchange, *Report of the President, May 1, 1926-May 1, 1927*, New York 1927, p. 69-70), which are more complete than the figures collected by the New York Federal Reserve Bank on the loans made by banks reporting daily in that city subsequent to October, 1917, show that in February and March, 1919, and again in the autumn of 1921, the total borrowings by the members of the New York Stock Exchange had fallen to less than one billion dollars. There were several reasons for this temporary decline. Prior to the war and the establishment of the Federal Reserve system bankers were accustomed to look upon call loans made to brokers as their principal secondary reserve, assuming that the funds so invested could always be obtained on short notice. Consequently a large supply of funds at low rates was available for collateral

call loans. This attitude of the banks and of other lenders was greatly modified through the closing of the New York Stock Exchange at the outbreak of the war in 1914, as a result of which it became practically impossible to realize on call loans. Thus a prejudice was created against dependence upon call loans as secondary reserves. Moreover the creation of the Federal Reserve system gave the member banks a new reservoir of funds to which they could resort when necessary. Call loans were reduced also because supplies of money which normally came from foreign banks were for a considerable length of time rendered unavailable by the war and post-war currency disorganization.

With the restoration of normal conditions after the war call loans have once more become liquid; in times of stress the Federal Reserve has helped to make them so. Europe has recovered financially to such an extent that when rates are attractive it has large sums available for the New York money market. Consequently brokers' loans have had a phenomenal rise, corresponding to the expansion of American industry, and there is every reason to believe that they will remain permanently upon a much higher level than that prevailing during the period 1914-21.

Loans to brokers in European financial centers are not as large in volume or as important a factor in the money market as brokers' loans in the United States. Here brokers' loans are significant in that they make possible security speculation for people of average means, who would neither wish to borrow on security collateral directly from the banks nor be in a position to do so. The reason for the lesser importance of brokers' loans in Europe is therefore to be found in the fact that security speculation abroad is not so popular as it has been in America particularly since the close of the war. Moreover since a great majority of stock exchange transactions in Europe are settled fortnightly or monthly and not daily as in New York, brokers handling term transactions need to borrow only for a period of two weeks or a month in order to finance those of their clients who wish to carry over their securities until the next settlement date. In London such loans are made by the joint stock banks and the merchant bankers. In Paris brokers receive most of their loans from the wealthy private banking firms, the *banques d'affaires* (investment banks) and some railway and industrial companies. In emergencies brokers may make fifteen and thirty-day loans to the full market value of their collateral

from the Caisse Commune, a common fund established by the *parquet* of the Paris Bourse. Brokers' loans are not important in Germany, where most of the security transactions are handled for their customers directly by the larger banks.

BROOK FARM (1841-46), an experiment in communal living at West Roxbury, Massachusetts, nine miles from Boston. It was founded as a joint stock company under the name of the "Brook Farm Institute of Agriculture and Education," but in January, 1844, it was reorganized as the "Brook Farm Phalanx of Agriculture, Domestic Industry, and the Mechanic Arts."

Of the numerous cooperative and communistic ventures that marked the middle years of the nineteenth century in America, Brook Farm by virtue of its distinguished intellectual and literary associations is much the best known. Although closely associated in the public mind with Transcendentalism it was rather a by-product of the many sided reform movements of the New England renaissance that synchronized with the rise of industrialism. The originator and directing mind was George Ripley (1802-80), a Unitarian minister and member of the Transcendental Club of Boston. He enlisted the interest of a notable group of writers including Emerson, Theodore Parker, Bronson Alcott, Orestes Brownson, William Henry Channing, Margaret Fuller, Elizabeth Peabody, Christopher Cranch, Nathaniel Hawthorne, Charles A. Dana and John S. Dwight. Of this list only Hawthorne, who used it as a setting for his somewhat critical *Blithedale*

Romance (Boston 1852), Dana and Dwight took up residence at the farm. The experiment had its inception in the dissatisfaction of these radical intellectuals with existing social conditions and the objective proposed was the substitution of cooperative for competitive labor. Primarily agricultural and educational in its first phase it later introduced the crafts of carpentry, cobbling and printing and engaged in manufacturing in a small way.

Its origins would seem to have been distinctly native and homely. The communistic theories of Saint-Simon, Owen and Fourier had no part in the original plan. Before 1840 there are few discoverable influences of such theories in New England. But with the appearance on the scene of Albert Brisbane, who while in Europe had become a disciple of Fourier, agitation began for a reorganization in accordance with the latter's unitary principles. Brisbane's *Social Destiny of Man* (Philadelphia 1840) seems to have exerted wide influence and under his guidance early in 1844 the community adopted a modified form of Fourieristic communism. The *Harbinger* (1845-49), a weekly magazine devoted to "social and political progress," was established to succeed the *Phalanx* (1843-45), and an adequate phalanstery to house the families was begun. Unfortunately the latter burned to the ground when nearly completed. The blow was heavy; after meeting its obligations the phalanx disbanded and the *Harbinger* was transferred to New York.

Neither socially nor financially had the venture borne the heavy loss that is often supposed. By common testimony life at Brook Farm was a stimulating experience, and the school in particular was a notable success.

BROOKE, JAMES (1806-68), British empire builder. Brooke came of a family which had prospered from East Indian activities, and his early life included service under the East India Company. In 1838 he sailed to explore the Malay Archipelago and establish trading relations. He had become convinced that Dutch

rule had been oppressive and would crumble before a liberal government and a conciliatory policy in any part of the East Indies. During a civil war in Borneo, Brooke aided the Sultan of Brunei against a rebellious vassal in Sarawak and was ultimately confirmed by the sultan as rajah of that territory. He aided British naval officers in the suppression of piracy, worked for the annexation to Great Britain of the island of Labuan (1846), of which he became governor, and was made British consul general for Borneo. In 1863 the British recognized Rajah Brooke of Sarawak as an independent sovereign.

His policy toward the Sarawak natives was chiefly that of non-exploitation. He abandoned the bulk of the revenues which had formerly belonged to the rajahship, ultimately even the head tax, and retained only a monopoly of antimony. In order to protect his native subjects from forced labor he tried to prevent the encroachments of independent European mercantile establishments. Although he abolished head hunting and piracy Brooke administered the bulk of native customs and law as he found them. His motives were misconstrued and violently attacked in England. But Brooke's rule in Sarawak was successful as an experiment in native administration rather than as a commercial venture. His policies stimulated ideals of colonial administration which have had wider application in portions of British West Africa.

BROSSES, CHARLES DE. See DE BROSSES, CHARLES.

BROUGHAM, LORD, HENRY PETER BROUGHAM (1778-1868), British parliamentary and social reformer. Brougham was graduated from the University of Edinburgh and was called to the English bar in 1808. He had already made a reputation as one of the earliest and most prolific contributors to the *Edinburgh Review* when the Whigs gave him a seat in the House of Commons in 1810. For the next twenty years, except for the period 1812-15, he was one of the unofficial leaders of the opposition. After his eloquent

defense of Queen Caroline in 1820 his power and popularity increased enormously until he left the Commons to become lord chancellor in the reform ministry of 1830. His *Life and Times* (3 vols., Edinburgh 1871) grossly exaggerates the importance of his own activities in the passage of the Reform Act. At the time of the struggle he was unable to swallow his objections to wholesale disfranchisement of close boroughs; and in any case his colleagues had learned to distrust his judgment and to disregard his advice. In 1835 Lord Melbourne condemned him to political extinction by leaving him out of his cabinet.

A political careerist, Brougham nevertheless accomplished much as a social reformer and his influence in molding public opinion is as important as his actual achievements. Concentrating his attention on non-party objects he perceived—as the aristocratic Whigs did not—the importance of appealing to the middle class electorate and the value of the press. In 1811 he secured the enactment of a law making possible the first effective prohibition of the slave trade, and after 1830 he took a great interest in the complete abolition of slavery. As a law reformer he was instrumental in the creation of the Judicial Committee of the Privy Council; he also labored hard to humanize the penal code, to simplify the laws and improve the administration of justice. He was one of the founders of the University of London. As a pioneer in popular education he partially fulfilled the program of his *Practical Observations upon the Education of the People* (London 1825) by founding mechanics' institutes and the Society for the Diffusion of Useful Knowledge (1827–44), which published under his auspices a *Penny Cyclopædia* (London 1833–43). His economic views persistently wavered. The *Inquiry into the Colonial Policy of the European Powers* (2 vols., Edinburgh 1803) was a moderate defense of the colonial system; but later Brougham intermittently advocated the repeal of the navigation laws. In 1812 he secured the repeal of the Orders in Council. Although he did not completely abandon agricultural protection until 1845 he was of some assistance in furthering the cause of free trade.

ARTHUR ASPINALL

Consult: Aspinall, Arthur, *Lord Brougham and the Whig Party*, University of Manchester Publications, Historical series, no. xlvii (Manchester 1927).

BROUSSE, PAUL (1844–1912), French socialist. Brousse, who was a physician, took part in

socialist propaganda at an early age. Self-exiled after the events of 1871, he sojourned successively in Spain, Switzerland and England. In Switzerland he met Bakunin, adopted his doctrines and worked with the Federation of the Jura. Upon his return to France after the amnesty Brousse became involved in the internal struggles of French socialism. At first he was a follower of Guesde and Lafargue, but he broke with them in 1882 at the Congress of St. Étienne and became one of the leaders of the *Fédération des Travailleurs Socialistes*, known as the "possibilist" group. This in turn was split into two factions in 1890, Brousse continuing as head of the federation and the more radical wing beginning a separate existence under the leadership of Allemane. The Broussist federation had considerable strength in some districts of Paris and in the west.

The "possibilist" program, as expounded by Brousse in his pamphlet *La propriété collective et les services publics* (Paris 1883) and in the weekly *Le prolétaire*, assumed that there are numerous stages in the advance toward the ultimate goal of socialism and accordingly called for a limitation at the outset to a series of practicable reforms. Brousse's interpretation of historical evolution, by which he buttressed this program, envisaged competition, the dominating and inevitable characteristic of the early phases of capitalism, giving way, with the victory of the better equipped producers over their rivals, to combination and monopoly. At this stage the state would step in, take possession of the monopolized industry and manage it as a public service. Just as the army, schools, highway maintenance and postal service had passed from private hands into public, so in the future would mines, railroads and eventually other industries. The active participation of Brousse and his followers in municipal, provincial and national politics was the logical corollary of this program.

PAUL LOUIS

BROWN, GEORGE (1818–80), Canadian journalist and statesman, one of the "Fathers of Confederation." After working with his father in sectarian journalism he founded in 1844 the *Toronto Globe*, which from the fifties to the eighties exercised a more powerful influence in molding public opinion than any other Canadian paper has ever possessed. Brown entered

public life in 1851 and became leader of the Upper Canada Reformers, or "Clear Grits," who in the fifties and sixties were essentially the radical agrarian party of what was then western Canada.

Representing "the intelligent yeomanry of Upper Canada" the *Globe* fought high tariffs, the undue influence of the Grand Trunk Railway and that working alliance between the French Catholic church and the business interests centering in Montreal which dominated Canadian politics. By his methods of controversy Brown did much to inflame sectional and religious feeling, especially in his successful campaign for the secularization of the clergy reserves and in his unsuccessful opposition to separate schools. On the other hand the *Globe's* constant summons to Canadians to rise to their opportunities did much to create that incipient national feeling which made possible the Dominion of 1867. Brown was one of the first Canadians to catch the vision of the West. From 1857 the *Globe* preached incessantly that Canada must absorb the Hudson's Bay Territory and become a great nation like the United States.

After his failure to procure "representation by population" as a solution of the relations of Canada East and Canada West, his generous action in joining his political opponents in the coalition government of 1864 insured the acceptance of confederation almost without opposition in Upper Canada. Defeated in the first Dominion election he was appointed to the senate a few years later. In his editorial capacity he remained until his death the real leader of the Reformers. The bitterness of its leader, who seemed destined to be found always on the side of political opposition, infected the party, which did not become really successful until it came under the more genial guidance of Laurier.

BROWNE, ROBERT (1550-1633), English clergyman, recognized during the past fifty years as the founder of Congregationalism in

England and America. Browne's personal direction was withdrawn from the movement in 1586 when he apparently conformed to the established church. After this time one must look to Browne's writings for his share of the influence which, according to Borgeaud's suggestion, radical Puritan ideas exerted on the development of early seventeenth century English and American political democracy. *A Booke which sheweth the life and manners of all True Christians* (Middelburgh 1582), containing the clearest statement of his ideas, is so far as is now known the first book written by an Englishman defending a full measure of religious liberty. He was also the first to maintain unequivocally that the separation of church and state is as necessary for the church as for the state. He taught that all authority is wholly dependent upon the will of the people, a term in which he included all classes of society.

M., *Congregationalism* (New York 1880) p. 61-128; Walker, Williston, *A History of the Congregational Churches in the United States*, American Church History series, vol. iii (New York 1894) p. 31-55; Cooch, G. P., *English Democratic Ideas in the Seventeenth Century* (2nd ed. with notes and appendices by H. J. Laski, Cambridge, Eng. 1927) p. 42-45; Borgeaud, Charles, "Premiers programmes de la démocratie moderne en Angleterre (1647-1649)" in *L'École Libre des Sciences Politiques, Annales*, vol. v (1890) 290-325, tr. by B. Hill as part of *Rise of Democracy in Old and New England* (London 1894).

BROWNSON, ORESTES AUGUSTUS (1803-76), American theologian and publicist. He had a remarkable religious and intellectual career which may be briefly summarized as follows: 1822, Presbyterian; 1826, Universalist minister and (1829) editor of the *Gospel Advocate*; 1830, freethinker and associate of Robert Dale Owen and Fanny Wright, lecturing in the interests of the Workingmen's party and contributing to the *Free Enquirer*; 1831, Unitarian minister and editor of the *Philanthropist*; 1836, organizer of "The Society for Christian Union and Progress," which was composed of working men and held its meetings in the Masonic Temple of Boston (he was a Freemason); 1838, founder and editor of the *Boston Quarterly Review* devoted to transcendental philosophy, Democratic politics and social reform (including the abolition of hereditary property); 1844, a convert to the Catholic church. From then on he devoted most of his energies to an aggressive

propaganda for Catholicism combined with American patriotism, publishing in addition to numerous books a large number of articles in *Brownson's Quarterly Review*, the *Catholic World*, the *New York Tablet* and the *American Catholic Quarterly Review*.

His early enthusiasm for radical reform was chilled by his failure to enlist the support of the working classes to his rationalistic humanitarianism. He therefore conceived "Christianity as a principle of reform" and, influenced by Benjamin Constant, the Saint-Simonians and Victor Cousin, he worked for "the religion of the future." He then came to the conviction that religion must be not the means but the end of social life and that "the church already is the new creation." At this point in his career he was much influenced by the philosophy of Gioberti and by the general enthusiasm among liberal Catholics for "popular liberty" under "Divine Sovereignty." He carried his theological liberalism to the point of attacking neoscholasticism and even of attempting to introduce his former Universalistic leanings into Catholicism. Opposition on the part of the clergy, followed by the Papal Syllabus of Errors, induced him to quit his theological polemics and confine himself to "public affairs." Accordingly he took an active part in political debate. He abandoned his southern Democratic friends on the secession issue and developed his theory of the "territorial sovereignty under God" of "the states collectively" as a platform for an uncompromising defense of the union combined with a liberal reconstruction policy and a decentralized government (see his *The American Republic*, New York 1866). His political fortunes and his *Review* suffered severely from his support of Fremont in 1864 against Lincoln as well as from his philosophic insistence on combining religious and political issues.

Consult: Brownson, Henry F., Orestes A. Brownson's . . . Life, 3 vols. (Detroit 1898-1900).

BRUCE, HENRY AUSTIN, BARON ABERDARE (1815-95), British statesman and educationist. He was born at Duffryn, Wales. In 1852 he entered the House of Commons as a Liberal and sat in the House for twenty years, holding many high political offices. His greatest parliamentary effort was the passing of the Licensing Bill of 1872. The vehement opposi-

tion of the vested interests concerned largely contributed to the Liberal rout at the succeeding election. He was made a peer in 1873, and withdrawing from party politics he devoted himself to social reform.

He was an opponent of radical political or economic changes and held that prosperity and education were the surest allies of progressive civilization. Anticipating the coming of great social dislocations he advocated the material and moral elevation of the masses. He served as chairman of the Royal Commission on the Aged Poor (1893) and on other public commissions concerned with reformatory and industrial schools, mines and education, and was one of the founders of the Social Science Congress. To him are chiefly due the reorganization of Welsh intermediate education and the establishment of a Welsh university. He was chairman of the Niger Company for many years and it was mainly because of his foresight and energy that a vast West African territory was added to the British Empire.

W. H. DAWSON

BRUCK, KARL LUDWIG VON, BARON (1798-1860), Austrian statesman and fiscal reformer. A native of Elberfeld in the Rhineland, he moved to Trieste in 1821 and there established the Austrian Lloyd shipping company. He was a member of the Frankfurt National Assembly of 1848-49, representing the Austrian "greater Germany" party of unionists. As minister of commerce and public works (1848-51) he cooperated in passing the constitution of March 4, 1849, and carried out a bold program of reforms. He reorganized the consular service as well as the post and telegraph services, introduced chambers of commerce and industry on the German model, built railways, improved the road and river transport system and codified the Austrian commercial and maritime law.

His great work, however, lay in the field of customs reform. He abolished many of the duties which retarded the development of national industry and established Austria and Hungary as a single customs territory with a uniform tariff. His further design of securing Austria's admission into the German customs union and of converting the latter into a Central European union which was to include Italy

and the Balkan peninsula was defeated by Prussian opposition, and Bruck had to be satisfied with favorable commercial treaty arrangements.

Bruck was raised to the nobility and in 1855 took over the portfolio of finance, but further reforms upon which his mind was set were frustrated by the Italian war. Accused by his enemies of complicity in army malversations he was dismissed in disgrace and committed suicide. A little later, however, the falsity of the charges was proved and officially proclaimed.

W. H. DAWSON

BRUIJN KOPS, JACOB LEONARD DE (1822-87), Dutch economist and statistician. After serving with the ministries of finance and of the interior he occupied for ten years (1864-73) the chair of economics and administrative law in the polytechnicum at Delft. From 1868 until his death he was a member of the lower house, where he frequently influenced government policies on economic and financial questions. Bruijn Kops was also active as author and editor. In 1850 he published *Beginnelsen van staathuishoudkunde* (5th ed. Amsterdam 1873), the first Dutch manual of economic principles, which enjoyed unusual popularity. He was the editor of *De economist*, a monthly concerned with practical economic problems, which was founded by him in 1852 and is still being published. After 1850 he was on the editorial board of the statistical yearbooks established by Bosch Kemper, and with the other members of the board he organized the Dutch statistical society in 1857. In the same year he published a statistical review of Dutch foreign trade from 1846 to 1855.

A liberal free trader, Bruijn Kops was essentially a practical economist. He advocated the abolition of import duties as economically harmful and of export bounties as an unjust privilege. He was opposed to taxation for social purposes and advised extreme caution in the use of public loans, which should be confined to the financing of permanent improvements. He conducted a vigorous campaign against consumption taxes, particularly those on necessities, and advocated the concentration of tax

collection in the hands of the national government.

Consult: Beaujon, A., in *Institut International de Statistique*, *Bulletin*, vol. iii, no. 1 (1888) 218-20.

BRUNETIÈRE, FERDINAND (1849-1906), French literary critic and social philosopher. Brunetière was professor at the École Normale, later editor-in-chief of the *Revue des deux mondes* and member of the French Academy. In *Le roman naturaliste* (Paris 1882) he made his debut as a critic in an attack on Zola and his naturalist school. A traditionalist and a classicist, he fought the impressionism and skepticism of Jules Lemaitre and Anatole France. Underlying his work was a conviction that the prevailing individualism and the absence of tradition and morality in the latter part of the nineteenth century were socially dangerous. In his *Histoire et littérature* (3 vols., Paris 1884-86), his *Études critiques* (8 vols., Paris 1880-1907) and in other critical works he set himself to the construction of a comprehensive system of criticism which would embody an integrated view of society. What he sought in society was unity and order, which he felt the science and the rationalism of his age were too bankrupt to provide. For Taine's system he substituted his *critique évolutionniste*, based on Darwinism, to explain the course of literary history; but as Irving Babbitt has aptly said, "in spite of his attempt at literary Darwinism Brunetière is not a scientist but a logician with a brilliant oratorical gift and a keen sense of historical development." Brunetière avoided the inconsistency of his rejection of science and his acceptance of an evolutionary theory of literature by ascribing to unknown causes the variations that took place (see *Discours de combat*, 3 vols., Paris 1900-07, and *Sur les chemins de la croyance*, Paris 1904). Comte had revealed to him not only the idea of a social organization of science and the humanitarian problem of the relation of man to man, but also the function and social importance of a church ("L'utilisation du positivisme" in *Sur les chemins*). What positivism failed to supply—a permanent and absolute foundation for society—Brunetière discovered at Rome in 1894. His famous article, "Après une visite au Vatican" (*Revue des deux mondes*, vol. cxxvii, 1895, p. 97-118), shows how Roman Catholicism offered him the basis on which the social hierarchy and order might rest. Brunetière found his refuge and his citadel in faith, of which he main-

tained that logic and dialectic must be the servants.

BRUNI, LEONARDO (c. 1374-1444), Italian humanist. Bruni is the most important representative of the early Italian trend which may be designated as the civic humanism of Florence. He was born in Arezzo, was in his earlier years secretary of the Curia, but lived in Florence continuously from 1415, received the rights of citizenship and was chancellor of the republic from 1427 until his death. Bruni's humanism was distinguished by his devoted study of the Greek city-state and of the ancient Roman Republic. The former he admired as the political model of the Florentine city-state of the Renaissance; the latter he felt to be the source of Italian civilization and imbued with that republican spirit on which was also founded the greatness of Florence. In the first book of his *Historiarum Florentini populi* (12 books, completed in 1439) the Renaissance city-state is portrayed as heir to the Roman Republic, the Roman Empire as the period of Italian decline and the German mediæval empire as an alien, barbarian rule. In his *De militia* (written 1421), confronted with the decline of the knightly class, he advocated the replacement of the usual Italian mercenaries by an arms-bearing citizenry modeled on that of the ancient republic.

His description of the government of Florence (*περὶ τῆς πολιτείας τῶν φλωρεντίνων*) is written entirely in Greek. Bruni's translations from the Greek, which include some of Plato's dialogues, many of the orations of Demosthenes and above all Aristotle's *Ethics* and *Politics* and the pseudo-Aristotelian *Economics*, were widely read during the fifteenth century. The Aristotelian writings constituted the Greek sources of Bruni's political theory. He was the first to translate Aristotle with philological accuracy, and his *Isagogicon moralis disciplinæ* (written 1421-24) defends the Aristotelian against the stoic ethics which had previously dominated humanism. In the field of education Bruni's widely read work, *De*

studiis et litteris (written 1422-29), was one of the first to develop a program of non-professional education which was based exclusively on the humanities and which was identical for both sexes.

HANS BARON

Consult: Woodward, W. H., *Vittorino da Feltrè and Other Humanist Educators* (Cambridge, Eng. 1897) p. 119-23; Beck, Franz, *Studien zu Leonardo Bruni*, Abhandlungen zur mittleren und neueren Geschichte series, vol. xxxvi (Berlin 1912); *Leonardo Bruni Aretino, humanistisch-philosophische Schriften*, ed. by Hans Baron (Leipzig 1928), containing a chronology of his works and letters.

BRUNNER, HEINRICH (1840-1915), German legal historian. He was an Austrian by birth and studied jurisprudence and history at Vienna, at the Institut für Österreichische Geschichtsforschung. As a pupil of Unger, Waitz and Sickel he laid the foundations for his subsequent method which, by linking the history of law with the auxiliary historical sciences and by evolving a new technique of research, profoundly influenced the science of German legal history. Brunner was the focus of legal historical research not only in Germany but throughout Europe. Although he taught first at the University of Vienna and later at the higher schools of Lemberg, Prague and Strasbourg, his influence was primarily felt in Berlin where he was active for over forty years and where at the academy he carried on the work of Eichhorn and Homeyer. As a director of cooperative scholarly publications he was prominently identified with all the more comprehensive projects of his time in the field of legal history, as for example, the *Deutsches Rechtswörterbuch* and the *Zeitschrift der Savigny-Stiftung für Rechtsgeschichte*. After the death of Waitz he took over in 1887 the *Leges* section of *Monumenta Germaniae historica*.

Brunner's main interest was the so-called Frankish period and the history of Germanic law in the earliest centuries. His success in demonstrating the Frankish origin of the Anglo-Norman jury trial established his reputation. Vassalage as the root of infeudation he traced back to the institution of the German *comitatus*. His crowning work, however, was his two volumes of a history of Germanic law, which unfortunately he did not complete. In the course of his investigation into the connection between early Germanic and late Roman law he came upon the so-called common law of the Roman provinces. This led him to the study of the survival of Germanic legal institutions in Italian, French,

Dutch and Anglo-Norman law. At the same time with rare intuition he traced certain legal ideas back into prehistoric times, e.g. inheritance and the representation of decedents.

BRUNO, GIORDANO (1548-1600), Italian philosopher. Accused of faults of discipline Bruno was forced to flee from the Dominican order. He wandered from city to city, first in Italy, then in northern Europe and England, arousing theological and philosophical hostility wherever he went. Bruno was the first to recognize that the fixed stars were other suns distributed through endless space, centers of solar systems inhabited by beings "perhaps better perhaps worse than we are." In three Italian dialogues purporting to have been published in Paris in 1584 Bruno presents these views with their philosophical consequences as an inevitable development from the "Copernican Revolution," which had occurred about four decades before, but a development so vast as to deserve the name of a "new philosophy." The astronomical theory involved in Bruno's system was absorbed, through Galileo, Kepler, Descartes and others, into the science of the seventeenth century and remains the foundation of all later world views.

By his new presentation of nature Bruno laid himself open to bitter opposition from every religious faith of his time, all of which were based on the conception of a single finite universe wherein two regions, heaven and earth, stood in complete contrast. In an effort to reconcile his astronomy with Christianity Bruno

evolved a pantheistic philosophy which, however, seemed to his day only an old heresy in a new guise. In 1592 he was denounced to the Venetian inquisition and later extradited to Rome, where he was burned on the Campo dei Fiori in 1600. Although the influence of his world view seems plainly traceable in the great seventeenth century systems of Spinoza and Leibnitz it was not until the end of the eighteenth century that the writings of Lessing and Jacobi brought a belated acknowledgment of his living service. In spite of his recantation at Venice, which he later retracted, his name, regarded as one of the foremost in the martyr-ology of intellectual freedom, has become a symbol for steadfastness in defense of truth.

EDGAR A. SINGER, JR.

Consult: Berti, D., *Giordano Bruno da Nola* (2nd ed. Turin 1889), containing all documents and a bibliography of Bruno's works; McIntyre, J. L., *Giordano Bruno* (London 1903), containing bibliography; Gentile, G., *Giordano Bruno e il pensiero del rinascimento* (Florence 1920).

BRUNS, KARL GEORG (1816-80), German jurist, pandectist and legal historian. Bruns was from the beginning an advocate of the movement for codification and strongly drawn toward modernism. He consequently sought to turn the existing historical school in a more contemporary direction in his very first major work, *Das Recht des Besitzes im Mittelalter und in der Gegenwart* (Tübingen 1848). He insisted that attempts to understand the pure Roman law must include the study of its modifications in mediaeval and modern times, thus establishing the so-called mediaevistic trend in Roman law studies. Later, however, Bruns turned more toward the study of the ancient Roman law. His editing of the *Fontes juris romani antiqui* (Tübingen 1860), the successive issues of which show the influence of Mommsen's critical method, testifies to the fact that he had already shifted his interest, a shift which is evident also in the two essays on the history of Roman law which Bruns wrote for Holtzendorff's *Encyklopädie der Rechtswissenschaft* (3 vols., Leipzig 1870): *Geschichte und Quellen des römischen Rechts* and *Das heutige römische Recht*. The change came about as a result of his dissatisfaction with Ihering's theory of possession, which he believed was not justified by the pure Roman law. Bruns upheld his view in his *Die Besitzklagen des römischen und heutigen Rechts* (Weimar 1874). He also wrote numerous essays, of

which one on Greek testamentary law shows his expanded range of interest in all ancient law. This is manifested more fully in his *Syrisch-römisches Rechtsbuch aus dem 5ten Jahrhundert* (Leipzig 1880), published in conjunction with the orientalist, Eduard Sachau. It was this work which provided the impetus toward subsequent research in Roman provincial law.

BRUNSWICK, TERÉZ, GRÖFNÖ (1775-1861), Hungarian educator and philanthropist. The beginnings of Countess Brunswick's liberalism may be traced to her father, a Hungarian nobleman, who taught her to admire Washington and Franklin. Perhaps the fact that she herself had not been subjected to the crushing influence of a school left her mind flexible for her educational work. The problem of bringing up the children of a widowed sister led her to seek out Pestalozzi in 1808. She became the lifelong devotee of the material and spiritual welfare of the children of the poorer classes, upon whom she felt the future of nations, particularly of Hungary, depended. Under the influence of Pestalozzi and Wilderspin she took advantage of the opportunity created by the Hungarian liberal movement led by Count Széchenyi to establish in Buda one of the first infant schools on the continent (1828). Other schools were soon founded and infant education in Hungary has its origin in her activities. Her pedagogical studies convinced her of the necessity for the spiritual and technical training of future teachers. Through her varied educational activities she played one of the most important roles in the diffusion of popular education in the nineteenth century. She also founded asylums of all kinds, among them workmen's homes in Hungary, Austria and Bavaria, and participated in the establishment of a European women's general welfare association which studied far reaching problems such as coeducation and eugenics. Her niece, Blanche Telcki, who attempted to continue her work, was involved in the Revolution of 1848. Countess Brunswick has been identified by some writers as the "immortal beloved" of Beethoven.

BRUUN, CHRISTOPHER ARNT (1839-1920), Norwegian educator. Bruun, a clergyman, was from early youth interested in religious and ethical problems. He denounced modern culture for its moral slackness, accused the Lutheran state church of mental sluggishness and narrowness and condemned the quality of contemporary religious life. Although a rather paradoxical idealism sometimes cut him off from vital contacts with values other than his own, it was just this idealism which deeply impressed Ihsen and Björnson, contemporary politicians, teachers and national leaders and, above all, Norwegian youth.

Inspired by Grundtvig in Denmark, in 1867 Bruun dedicated himself to an ambitious plan for folk high schools (*Folkehøiskoler*), similar to the one established three years earlier at Sagatun. These schools, one of which Bruun founded at Wonheim and directed for many years, were for peasants of eighteen and upwards. They aimed to awaken latent intellectual powers, to stimulate the national culture and to develop a free and rounded conception of life. Teaching was mostly through discussion and was aimed at neither examinations nor economic advancement.

The schools met strong opposition from orthodox religious leaders, pietists and rationalists and for long failed to obtain state support. Consequently the movement had difficulty in competing with the more utilitarian county schools, which obtained government subsidies. Bruun carried on a determined campaign, however, and by 1876 won some support from the state. After his death the schools Bruun had fostered were granted larger governmental appropriations than the county institutions and for the first time exceeded them in number.

BRYAN, WILLIAM JENNINGS (1860-1925), American political figure. His early training was intensely religious and his formal education was of an oratorical and moralistic nature, scientific training being conspicuously absent. He was trained for the law but was never successful at it, and the quest of a law practise brought him from Illinois to Lincoln, Nebraska, where he took active part in local politics. In his youth he had come into contact with agrarian discontent and in his early campaigns in Nebraska he designedly and by inclination made more of an appeal to the farmers than to the city workers and the townsmen. He had a Jeffersonian certainty that the farming classes were the backbone of the nation, but there is no evidence that he ever understood the difficulties of the urban factory workers. His firm belief in the unique importance of the farming class led him to accept their own remedies for their difficulties as true and adequate solutions. He became thus the greatest political exponent of American agrarian discontent, predicating his entire political career upon it and introducing agrarianism into the Democratic party. As congressman (1890-94) he came into national notice as an advocate of free trade and free silver, both measures being designed to benefit the farmers. His failure to receive the nomination for a third term in Congress released him for a skilfully managed propaganda in favor of the coinage of silver at the ratio of sixteen to one which resulted in his nomination for the presidency on the Democratic ticket in 1896.

The campaign that followed brought out the personal bases of his immense popularity, his unusual capacity for emotional oratory and his ability to cover enormous distances without apparent fatigue. He was the outstanding leader of the Democratic party from 1896 to 1915 and its candidate for the presidency in 1896, 1900 and 1908. He never achieved the presidential office, largely because he did not appeal to the urban voters, who felt that their interests were better served by the plutocracy or by other leaders. But despite his formal failure he was of real significance as the champion of the masses and as an advocate of the staple measures of political liberalism of his day. In his speeches and in his journal, the *Commoner*, which he conducted from 1901 to 1923, he advocated free trade, free silver, an income tax, prohibition, trust control, eventual government ownership of railways, woman's suffrage, abstention from

imperialism, and international arbitration. His social creed was "the man against the dollar," and such an attitude made him an implacable enemy of concentrated wealth as symbolized by Wall Street. His influence on national legislation, through the Democratic senators and representatives in Republican administrations and his own part in the Wilson administration, was considerable. He even forced the dominant Republican party to deal with many of the issues he raised. In the Wilson cabinet Bryan became secretary of state, serving from March 4, 1913, to June 9, 1915, and resigning because he felt Wilson was moving toward participation in the World War.

Bryan's strength lay in a sensitivity to the aspirations of the disinherited, which, while it furnished the emotional drive for his political liberalism, led him also to an unmitigated belief that "the voice of the people is the voice of God." In economics, social morals or religion he rejected the intellectual formulations of his day and preferred the emotional common sense and tradition of the ordinary citizen to the analysis of the expert. After the war years and as he grew older his moral and religious interests gained the upper hand, and his closing years were made vivid by his campaign against the teaching of the doctrine of evolution in publicly supported schools, a campaign which reached a climax in the Dayton trial of 1925.

C. HARTLEY GRATTAN

Consult: Bryan, W. J. and M. B., *The Memoirs of William Jennings Bryan* (Philadelphia 1925), incomplete and on some matters inaccurate, Hibben, P., and Grattan, C. H., *The Peerless Leader: William Jennings Bryan* (New York 1929); Merriam, C. E., *Four American Party Leaders* (New York 1926) p. 63-84; *The American Secretaries of State and their Diplomacy*, ed. by Samuel Flagg Bemis, 10 vols. (New York 1927-29) vol. x, p. 3-44.

BRYANT, WILLIAM CULLEN (1794-1878), American journalist and poet. He was born of cultivated Puritan stock at Cummington in a part of western Massachusetts which retained many frontier characteristics. In 1810 he entered Williams College where, disappointed by the meager instruction, he remained less than a year. Law study, admission to the bar, discontented efforts to practise in Great Barrington, verse writing and marriage followed. He found the law "shabby," but within a few years made a national reputation by his poetry. He took up magazine work in New York in 1825, became assistant editor of the *Evening Post* in 1826 and

in 1829 succeeded William Coleman as editor, a position which he held until his death. He did much to elevate journalism and gave the *Evening Post* an influence out of all proportion to its slender circulation.

Bryant was early involved in the Jacksonian movement, which became strong not only on the frontier but among urban workingmen, and in his editorial capacity he gave vigorous support to the principal doctrines of Jacksonian democracy. In his radical position on the relations between government and corporations, in his hostility to Chief Justice Marshall and other centralizing leaders and in his slashing support of labor unions against hostile courts he was much influenced by William Leggett. During the period 1835–37 Bryant assailed the inflation and speculation of the time; he also attacked all infringements on free speech, free mails and free publishing, especially as regarded abolitionists. His association with the Democratic party lasted till 1844 when his opposition to slavery brought about a growing divergence; in 1848 he was a leader in forming and supporting the Free Soil party. In the decade before the Civil War he and his associate John Bigelow were among the most fiery antagonists of the expansion of slavery and advocates of Republican doctrine. During the war he took a "radical" stand, urging emancipation and other aggressive measures, but after its close he stood for a mild reconstruction policy and in 1872 supported the Liberal Republican movement until the nomination of Greeley disgusted him. In later years he showed equal zeal for tariff and civil service reform.

BRYCE, JAMES (1838–1922), English historian, political theorist and statesman. He was a shrewd and tireless observer of life who sought, through a varied experience of his own, through conversation and inquiry and through constant travel, to understand fully the world in which he lived. He was always an indefatigable traveler—in the Caucasus, in South America, in South Africa and all the British dominions. Of him, as of the mediaeval Em-

peror Frederick II, it may almost be said that he was *universalis in omnibus rebus*.

As a historian of political institutions he must stand by his book on the *Holy Roman Empire* (London 1864, new ed. New York 1904), which is a permanent work of interpretative insight. As a commentator on modern democracy he has left the classical work on *The American Commonwealth* (2 vols., London 1888; new ed. New York 1910) and two volumes on *Modern Democracies* (2 vols., New York 1921). They show a rich descriptive gift; they contain the fruits of constant research conducted less in the study or by investigation of documents than by first hand inquiry and actual observation of the working of institutions. In his sociological method he went straight to the human factors which interested a deeply political mind—the quality of the human material in parliaments and assemblies, the methods of party organization and action, the character of a country's press, the influence of money in its politics. In one sense he was not systematic: he ranged freely from topic to topic; but the nature of his varied discourse had its analogy with the multiplicity of life itself. The work of Bryce as a jurist, represented by his two volumes of *Studies in History and Jurisprudence* (Oxford 1901), did much in a descriptive and analytic way to develop the concepts of comparative jurisprudence to which Sir Henry Maine had given such an impetus. In general his range as a writer was catholic: he could compare the Roman Empire with the British, and Roman law with English, at the same time that he could discourse on primitive Iceland or analyze the constitutions of the Boer republics in South Africa. He was always shrewd; he was generally just and accurate; but he tended to be diffuse, and the volume of his influence might perhaps have been greater if his work had been less voluminous.

As a Liberal politician and statesman he served for long years in Parliament and sat in cabinets. He belonged to a constellation (Morley, Haldane, Asquith, Grey) which was remarkable in the annals of British politics. His affinities were with Morley and Haldane; and like them both he combined (as Balfour on the Conservative side has also combined) the life of the scholar and the life of the politician. Less philosophic and less deductive than Morley or Haldane he had a richer grasp of facts and probably a deeper understanding of the people at large and the real world outside the study. Yet perhaps he lacked, as they lacked, construc-

tive political imagination and popular appeal. In the world of diplomacy and of international relations he played a part by which he will not least be remembered. The master who had written *The American Commonwealth*, the ready talker and eager inquirer, the great repository of knowledge, he was naturally a great ambassador to the American people; and his work in interpreting this people and the English people to one another was a basis for a new era of mutual understanding. In his latter days he interested himself deeply in the problems of international peace; he followed both the American and the British plans for the solution of those problems, corresponding particularly with friends in America; and he may be counted among those whose labors helped to produce the new international spirit of our days.

BUBBLES, SPECULATIVE. The term bubble came into use early in the eighteenth century as descriptive of the more highly speculative joint stock undertakings of the period. Blackstone narrowly defines as bubbles "all unwarrantable undertakings by unlawful subscription." But the term has since acquired a more general application, and is used with reference to any situation in which the cumulative effect of widespread speculation has been to enhance prices to a point having no apparent relation to the object of the speculation.

The three outstanding bubbles in history are the tulip mania in Holland, the Mississippi scheme in France and the South Sea bubble in England. All three came before any considerable development of organized speculation. They were made possible in large measure by general ignorance concerning economic phenomena, particularly the little understood but rapidly expanding field of credit.

The tulip mania in Holland reached its height in 1636 and 1637 toward the end of a prolonged period of prosperity. The culture of tulips began to assume importance in Holland early in the seventeenth century, and until the beginning of 1634 trading was limited to professional growers and experts. In 1634 the public entered the market. All classes of the population joined in the excitement; in fact the speculation was carried on chiefly by persons quite outside the ordinary tulip trade. The mania spread to some extent to London and Paris. Starting in the middle of 1635 prices advanced with increasing rapidity. A pound Witte Croonen, for example, which cost \$50, was sold for \$1440. The markets underwent a rapid evolution. During the boom period in 1636 neither payment nor delivery was made at the time of closing the transaction. By the middle of 1636 most transactions took place without basis on either side. The seller sold bulbs which he did not possess for a promise of money which the purchaser did not possess. Paper profits were therefore tremendous and contributed greatly toward heightening the mania. Speculation degenerated into sheer craze during the autumn of 1636, and the crisis came suddenly on February 3, 1637. Prices collapsed. The government endeavored unsuccessfully to straighten out the resulting chaos of broken agreements and canceled contracts. The situation was only gradually cleared as various cities took steps of one kind or another. While the crisis was a shock to the economic structure, it did not have serious after effects. Few important merchants or large companies had been involved. It had been built up largely on a credit basis among individuals, and the collapse of the structure resulted more in psychological than in economic anguish.

The Mississippi scheme is perhaps the greatest speculation in a single company that has ever occurred. Its creator, John Law, was a Scot who gained considerable prestige in French financial circles owing to the success of his Banque Générale, founded in 1716, which in addition to other banking operations engaged in the issue of banknotes. In 1717 Law founded the Compagnie de la Louisiane ou d'Occident, which took over the grant for Mississippi trade held by Antoine Crozat, as well as the Compagnie du Canada. Its capital was subscribed one fourth in coin and three fourths in *billet d'état*, the depreciated government paper of the time. At first the depreciation of government paper and the determined opposition of power-

ful enemies drove down the value of the new company's shares, and for about one year the 500 livre shares sold for about 300. In September, 1718, however, the Compagnie d'Occident acquired the monopoly of tobacco from the crown. Furthermore, Law's Banque Générale was transformed into the Banque Royale, with Law as director and the king guaranteeing its notes. During 1719 other companies with special grants for foreign trade were absorbed and the company obtained control of the mint, undertook the payment of the national debt and received the grant to collect taxes. This expansion required additional capital. Law adopted a plan similar to the modern method of stock rights, in which every holder of four original shares (*mères*) could purchase one of the new shares (*filles*) at a premium. Payments were spread over a twenty-month period. The first issue early in 1719 was made with a premium charge of 50 livres per 500 livre share. The price of shares rose to 750. The second issue in the summer required a premium of 500 livres, and the price advanced again. In October the third issue, made at a premium of 4500 livres, was oversubscribed, and the shares sold at 8000. Paris had become the center of speculation for the entire world. It is estimated that over 300,000 persons came to the city during September and October, 1719. The increased population and the general recklessness in money matters which usually accompanies these bubbles led to great activity in trade and industry. On January 5, 1720, Law became controller general of the finances, and individual shares in the Compagnie d'Occident reached 18,000 livres in value. But confidence began to dwindle. Foreign speculators withdrew their gains in bullion. People began to sell shares. By various methods Law endeavored to maintain the price of the stock, and finally he declared it fixed at 9000 livres. This transferred the panic to the banknotes, and there was a rapid increase in their circulation. The bank was compelled to suspend payments, and Law went into hiding. The people were enraged, and the government endeavored to meet the situation by a number of actions against persons who in one way or another might be held responsible for the bubble. Both the bank and the company were destroyed.

Perhaps the best known bubble is that connected with the South Sea Company. In 1711 there was incorporated in England a new undertaking known as the "Governor and Company

of the merchants of Great Britain, trading to the South Seas and other parts of America and for Encouragement of the fishing." The company took over nearly £ 10,000,000 of public debt, on which it was to receive 6 percent, secured by certain permanent duties. In exchange it was granted a monopoly of British trade with South America and the Pacific Islands. In 1713 the company received a monopoly of the lucrative slave traffic with Spanish America. The undertaking was only moderately successful. Late in 1719 it embarked on the more ambitious project of taking over the entire national debt. The Bank of England immediately made a counter offer; but the bid of the South Sea Company was accepted. This involved an offer to the government of £ 7,567,500 for the privilege of taking over the national debt of £ 30,981,712, on which the government was to pay 5 percent for seven years, and then 4 percent. The aim of the directors was to persuade the persons holding the debt, of which a large part was in the form of terminable annuities, to exchange it for South Sea stock. The stock, which was to be issued at a high premium, would extinguish a large amount of annuities with a small amount (par value) of stock. The enabling act of Parliament was not passed until April, 1720.

In the meantime there was a new development, the promotion of new companies. In 1717 the share capital of existing companies had slightly exceeded £ 20,000,000, of which one half was in the South Sea Company and one fourth in the Bank of England. Late in 1719 people encouraged by the success of the existing companies began to purchase stock in new enterprises. Subscribing for stock was made easy, the prospective purchasers being required to pay only a small fraction of par value. During January, 1720, there was uncertainty concerning the new proposal of the South Sea Company, and the interest of speculators turned to new ventures. In February the nominal capital in new companies exceeded £ 30,000,000. It became evident during this month that the debt would probably be sold to the South Sea Company, and its stock advanced from 128 to 187. An inquiry into the new subscriptions was undertaken by Parliament, which undoubtedly checked somewhat the excitement of the speculators; but the advance was resumed in the middle of March. The advance was cumulative in the case of South Sea stock because the higher the market price of the stock, the greater was the profit to be made on the debt conversion.

On March 18, 200 was reached; and in April, when stock was offered to the public and the debt conversion had begun, the price was over 400. In a few weeks more than half the annuitants had consented to convert.

Speculation was spreading rapidly to other fields, and there was a fresh outburst of new promotions during April. The earlier period had seen for the most part ventures in fishing, insurance and finance. The new enterprises were for foreign and colonial commerce. The speculation became most intense from May 20 to June 24. South Sea stock advanced to 800, and new enterprises with any promise advanced to large premiums. The total capital of new companies floated during the single week ending June 11 was £224,000,000. Many of these new companies were fantastic. Some of the purposes stated were: to fish for wrecks on the Irish coast, to make salt water fresh, to make oil from sun flower seeds, to import a number of large jackasses from Spain, to manufacture a wheel of perpetual motion. The directors of the South Sea Company were concerned with making more funds available for investment in their shares. They loaned funds to prospective purchasers, holding the stock as collateral, but they also used their influence to check the volume of new companies which were competing with them for capital. As a result, the Bubble Act (par. 18, 6 George I., c. 18) was passed declaring these new enterprises subject to legal punishment if not fundamentally sound.

Late in June South Sea stock reached its peak at 1050. At this time England was interested only in security prices. Everyone came to Exchange Alley to buy and sell stock. But in August the fall began. The insiders were mostly out, and word of their withdrawal made the collapse more certain. Furthermore a legal attack brought by the South Sea Company against certain other companies was such a shock to credit that it rebounded against the value of South Sea stock. At first the decline was chiefly in the new companies; but in September, 1720, South Sea stock fell from over 700 to below 180.

Although the whole affair was primarily financial it brought serious business depression in its wake. An inquiry by Parliament disclosed fraud and corruption in the conduct of the South Sea Company. Certain government officials were fined or imprisoned. The estates of the directors were confiscated, about four fifths being devoted to the relief of the sufferers. The greatest losers were probably the annuitants who

had accepted the offer to exchange. They eventually received about one half the original value of their annuities.

Although there have been no bubbles in recent times which can compare with the three just described, speculative crazes still exist. In England prior to the crisis of 1825 the speculation in new companies was nearly as wild as in the South Sea bubble. Over 600 new joint stock companies were formed requiring £372,000,000 share capital, and prices of established companies went skyrocketing. There was a similar era of promotion ending in 1866, but it was much less extravagant. In the United States railroad speculation approached bubble proportions between the Civil War and 1873. The mulberry tree "craze" of the thirties, the "hen fever" of the fifties, the gold or Kaffir boom in the nineties, the rubber boom in 1910 and the Florida land boom of 1925 must also be mentioned.

In recent years bubbles have often been related to new industries. In the very nature of the case there are no past records concerning similar enterprises which can be taken by prospective investors as a basis for judgment. The new companies require capital for their development, and consequently the investment bankers are often enlisted on their side, using all available methods to convince investors of the promise of the new industry. The development of turnpikes, canals and banks played an important part in the bubble which burst in 1825. The expansion of railroads during the period from the sixties to the eighties and the growth of the electrical industry both possessed the necessary appeal to the speculative interest. Since the war the development of aviation companies has followed the same course. Many investors failed to differentiate between aviation records and aviation profits. As a result the speculative period of 1928-29 saw 33 companies listed on the New York Stock Exchange and Curb Exchange whose securities reached a value of \$1,160,000,000, only to decline in the ensuing period to \$284,000,000.

At present waves in speculative interest appear to be one of the most evident characteristics of the business cycle. The marked advance in security prices during 1928-29 was supported by the psychological optimism of a period of prosperity. The marked increase in publicity given by newspapers to financial news and the application of high pressure salesmanship to securities further enhanced the intensity of the situation. On the other hand the rapid development of paraphernalia for speculation—stock

exchanges, brokerage houses—has eliminated some of the difficulties in the way of widespread speculative activity. The extensive use of credit through margin accounts and call loans is another modern phenomenon which tends to stimulate speculative interest. There is, however, some tendency to exaggerate the part played by the speculative element in the business cycle. Stock speculation is a symptom rather than a basic cause. It may exaggerate the crisis, but its chief importance lies in its effect on the psychology of business men.

The bubble is fundamentally a psychological phenomenon. It is based on the principle of projection. The speculator is aware of past advances of price. He is therefore convinced of future advances in prices. He purchases with no intent other than resale at a higher price, seldom considering the economic forces in the situation. He sees only the anticipated profit. The character of his position, emotional rather than rational, makes him extremely susceptible to rumor, and assures a severe crisis when the reaction sets in.

BUcareli Y URSÚA, ANTONIO MARÍA (1717-79), viceroy of New Spain (Mexico) and "father" of the present American state of California. Bucareli was born in Spain and entered the army, rising to the rank of lieutenant general. He served also as governor and captain general of Cuba and was appointed viceroy of New Spain in 1771. A man of the highest character, he was also endowed with extraordinary abilities and is considered one of the best of the Spanish viceroys. His greatest work was on behalf of Alta California, as California was then called, where in 1769 after two hundred and fifty years of effort the Spaniards had at length founded settlements. After a precarious existence of four years these establishments were on

the point of being abandoned in 1773, but were saved by a remarkable series of constructive measures on the part of Bucareli. Most important of these was the opening of a land route, which under conditions as they existed in those days was the only way that settlers and the other elements of a permanent establishment could be sent to the province. These measures culminated in the founding of San Francisco in 1776. In that same year California was taken out of his hands and included in a new government of the frontier provinces. In consequence the overland route was neglected and the development of population of the province which Bucareli's measures promised to effect never materialized. He had saved California from falling into the hands of England or Russia, which might have hindered its acquisition by the United States, but he was not permitted to give California a chance to become ineradicably Hispanic, perhaps eventually a Spanish American republic. The negligence of his successor served virtually to hold the land in trust for the later occupation by the United States.

BUCHANAN, DAVID (1779-1848), Scottish economist. His most important work was his annotated edition of Adam Smith's *Wealth of Nations*, with a supplementary volume entitled *Observations on the Subjects Treated of in Dr. Smith's Inquiry . . .* (Edinburgh 1814). This volume presents many acute criticisms of Adam Smith, particularly of his rent theories, and advances an argument for progressive taxation on the ground that a proportional rate works a hardship upon the recipients of small incomes.

In 1844 he published an *Inquiry into the Taxation and Commercial Policy of Great Britain* (Edinburgh), a work in which he favored free trade and criticized the existing system of taxation. He was opposed to taxing manufactured goods, and although he accepted the income tax in principle he held that it was indefensible in practise since it allowed inequitable assessment and evasion and was inconsistent with the "spirit of freedom." Believing that rent was due to the monopolistic ownership of land Buchanan attacked in this book the Ricardian theory of differential rent as "a skilfully disguised fallacy."

W. H. DAWSON

Consult: Cannan, Edwin, *A History of the Theories of*

Production and Distribution (3rd ed. London 1924); Seligman, E. R. A., *The Shifting and Incidence of Taxation* (5th ed. New York 1927) p. 149, 195, and *Progressive Taxation in Theory and Practice* (2nd ed. Princeton 1908) p. 259.

BUCHANAN, GEORGE (1506-82), Scottish humanist, historian and political philosopher. He was educated at Paris and at St. Andrews and spent most of his life as a wandering scholar, teacher and poet. His political thought is foreshadowed in his Latin tragedy *Baptistes* (written about 1541), which discusses the rights of reformers to resist authority and is an acute psychological study of the mixed motives against which they have to contend. Returning to Scotland in 1561 Buchanan joined the Reformed church, served as lay member of several of its general assemblies and in 1568-69 sat on the commission sent to England by the reformers to state their case against Mary Queen of Scots—a case which he later presented to European public opinion in his *De Maria scotorum regina*, commonly known as *Detectio* (London 1571?). From 1570 until his death he was tutor to the young king James VI. Besides his classical if not unparitisan *Rerum scoticarum historia* (Edinburgh 1582), primarily valuable as a record of his own time, Buchanan's chief prose work was *De jure regni apud Scotos* (Edinburgh 1579, tr. into English by Robert Macfarlan, Edinburgh 1799). It was written between 1567 and 1570 and circulated in manuscript, so that it antedated the writings of the French monarchomachs. It is usual to say that the *De jure* contains no novel contributions because it is built on a foundation of mediaeval conceptions, the subordination of the king to law, the compact between king and people and the right to depose the king for breach of the compact. Actually Buchanan's development of these ideas makes his work the most modern between Machiavelli and Hobbes. The law to which the king is subject is positive law, enacted by the national legislative assembly and requiring constant change and experiment in the process of giving content to natural law, which Buchanan regards as merely a sense of justice. The function of the king is little more than to serve as a public example of good morals. Buchanan is one of the earliest writers to accept expressly the theory of majority rule. Answers to *De jure* were published by Blackwood, Wyznet and Barclay. In the next century it had a great vogue among opponents of royal absolutism.

JOHN DICKINSON

Consult: Brown, Peter Hume, *George Buchanan*,

Humanist and Reformer (Edinburgh 1906); Glasgow-Buchanan Quatercentenary Committee, *George Buchanan: Glasgow Quatercentenary Studies 1906* (Glasgow 1907), containing complete bibliography of Buchanan's works and works about him, as well as an analysis of the *De jure* by W. G. MacKenzie; *George Buchanan: a Memorial*, ed. by D. A. Millar (St. Andrews 1907).

BUCHANAN, GEORGE (1831-95), British public health authority. He was the son of a London practitioner of Scottish origin and graduated in 1855 from the University of London. He was a physician at the London Fever Hospital from 1861 to 1868, a period when "fever," largely typhus, was still endemic and frequently epidemic in London and had become the chief concern of public health authorities. In 1857 Buchanan was appointed medical health officer to the crowded, poverty stricken London parish of St. Giles. His early reports on conditions in this parish deserve comparison with the reports for the entire city made by John Simon. In 1869 Buchanan became permanent inspector of the Privy Council, of which Simon was medical officer; he was soon transferred with Simon to the newly formed Local Government Board and eventually succeeded the latter as the medical officer of this board. In the course of his work for the Privy Council Buchanan prepared an official report on the decrease of mortality in twenty-five towns, following the installation of main drainage works and the provision of public water supplies. The report pointed out the decline in typhoid fever and pulmonary phthisis with the decrease in the dampness of the soil. In a subsequent study of the vital statistics of certain areas in the south-east of England, Buchanan discovered an excess of phthisis in the districts of impervious soils as compared with districts of porous soils. Those investigations had considerable influence on the medical opinion of the day and were described by Simon as having "become classical in sanitary literature." Although the conclusions based on them must be modified in the light of modern knowledge of both tuberculosis and statistical method, the preference for porous soils still exists even if the directness of the causal relationship is questioned.

ARTHUR NEWSHOLME

BUCHANAN, JOSEPH RAY (1851-1924), American labor leader. Born in Missouri and a printer by trade he was drawn to Colorado in 1878 by the "Leadville Fever." The railroad

brought cheap labor and wage cuts to Leadville, and Buchanan found himself on the street corners agitating for striking miners. From Leadville he moved to Denver, where he started a small paper, the *Labor Enquirer*, and acquired sufficient fame to be named Rocky Mountain representative of the International Workingmen's Association in 1883. The depression of 1884-85 and the receiverships into which speculation had thrown the western railroads brought on a series of wage reductions for the shopmen. In May, 1884, the Union Pacific shopmen walked out and appealed to Buchanan for leadership. He organized them into assemblies of the Knights of Labor, which he had joined through his affiliation with the Typographical Union, and won the strike. Within a year four great railroad strikes were fought, and his leadership of the famous strike on the Denver and Rio Grande Railroad and the victory over Jay Gould won for Buchanan a place on the general executive board of the Knights of Labor, then at the height of its power. He broke with Powderly in 1886 over the expulsion of the Cigar Makers from the order and attempted to lead a secession when he was excluded from the Minneapolis General Assembly. He was active in the movement to save the men sentenced in the Haymarket bomb affair, in the People's (Populist) party and for a time in the Socialist Labor party. In 1892 and again in 1894 he attempted to unite the scattered forces of labor but without success.

His autobiography, *The Story of a Labor Agitator* (New York 1903), reveals a romantic individualist who could find no place in party or organization demanding regularity and assent. His life and adventures probably best epitomize the type of labor agitation and revolt which first made its appearance in the far West.

BUCHENBERGER, ADOLF (1848-1904), German statesman and agricultural economist. After completing a course in cameral science Buchenberger entered public life in Baden in the seventies, and after 1893 served as its finance minister. It was largely due to his broad concept of the office that Baden was known as the best governed of the south German states.

Buchenberger approached the problems of government scientifically. He was most interested in questions of agricultural policy growing

out of the rise of economic protectionism in Germany, such as the development of new crops, better credit facilities, a lightening of taxation on agriculture and other measures for improving the conditions of the peasant and small landholding class. In 1882 and 1883 he conducted a thorough statistical survey of the agricultural situation in Baden which was unique in its field and became the model for similar undertakings by other territories. As part of Adolph Wagner's voluminous *Lehr- und Handbuch der politischen Ökonomie*, he wrote *Agrarwesen und Agrarpolitik* (2 vols., Leipzig 1892-93), the standard work of the period on German agricultural policy. It is remarkable both for its erudition and for its judgments, and many sections are still considered authoritative. The theory of economic individualism is contrasted with a program for systematic state intervention in favor of agriculture, carefully moderated so that the sense of individual responsibility would not be weakened by the supervising activity of the state. Under the title *Grundzüge der deutschen Agrarpolitik* (Berlin 1897, 2nd ed. 1899) Buchenberger gave a condensed, popularized account of the premises and the aims of his agricultural policy.

BUCHÉZ, PHILIPPE JOSEPH BENJAMIN (1776-1860), French social philosopher. After the failure of the Carbonari movement, in which he had taken a prominent part, Buchez became converted to Saint-Simonism; this too he renounced in 1829 because he disapproved of the pantheistic religious doctrines of Bazard and Enfantin. His own social philosophy is presented in the *Introduction à la science de l'histoire* (Paris 1833; 2nd ed. 2 vols., 1842), and the *Essai d'un traité complet de philosophie, du point de vue de catholicisme et du progrès* (3 vols., Paris 1838-40). During the Revolution of 1848 he was elected to the Constituent Assembly, of which he became president on May 4 as a representative of the moderate wing. His influence as a politician was slight and after the revolution he retired into private life.

The basis of Buchez' philosophy is the conception of continuous progress through successive stages of history. The last stage was initiated by the revelation of the Christian religion and will be completed when the precepts of Christ, equality, fraternity, charity, have been applied

to social organization. Since, as he believes, the church has failed in its mission, other forces must accomplish its work. Buchez' sympathy with the achievements of the French Revolution was expressed in *Histoire parlementaire de la révolution française* (40 vols., Paris 1834-38; 2nd ed. 6 vols., 1846), a vast collection of documents which he edited in collaboration with Roux-Lavergne. Accepting the revolution, he nevertheless condemned violence. Here as elsewhere his political doctrines, like those of other French democrats under the bourgeois monarchy, are somewhat vague and confused. As a practical measure of reform Buchez advocated, especially in his publication *L'européen*, that working men form associations to assume control of raw materials and the tools of production. Thus he may be regarded as a founder of the producers' cooperative movement. The working class newspaper *L'atelier* (1840-50) derived its inspiration from Buchez' ideas, while his theoretical writings exercised an important influence on J. M. Ludlow and other English Christian Socialists.

(Paris 1866); Castella, G., *Buchez historien* (Fribourg 1909); Cuvillier, Armand, "Buchez, le fondateur en France de l'association ouvrière de production" in *Revue des études coopératives*, vol. i (1922) 356-71; Weill, Georges, *Histoire du parti républicain en France de 1814 à 1870* (Paris 1900).

BÜCHNER, LUDWIG (1824-99), German philosopher. Brother of the revolutionary dramatist, Georg Büchner, he was a leader in the *Materialismustreit* which raged in Germany in the last half of the nineteenth century. He had been trained as a physician and after his dismissal from the University of Tübingen caused by the publication of his *Kraft und Stoff* (Frankfurt 1855, 21st ed. Leipsic 1904; tr. by J. F. Collingwood London 1864, 4th English ed. from 15th German ed. London 1884) devoted himself to study, scientific popularization and social agitation.

Büchner's materialism pretended to be the logical corollary of the exact and biological sciences. Together with Vogt and Moleschott he regarded the categories of mechanics—force, matter and motion—as fundamental, explanatory terms to which everything could be reduced.

The real import of his theory was its opposition to dualism of the metaphysical religious variety.

In order to combat religious dogmas more effectively it erected into opposing dogmas the tentative results won by the science of its own day. In discussing social and political questions it appealed not to revelation but to the laboratory and, after Darwin, to the workshops of nature. Büchner never worked out a consistent theory of materialism. He characterized his position as "realistic monism" in contrast to the dualistic idealism which was the current state philosophy. He won adherents among the rank and file of the German Social Democrats by virtue of the negative impact of his "militant naturalism" rather than by anything positive. Marxian theoreticians (e.g. *vide* K. Kautsky's *Materialistische Geschichtsauffassung*, Berlin 1929), following Engels' lead, have dubbed his standpoint "vulgar materialism," condemning its mechanism, its unhistorical character and its sentimental ethical tendencies. Büchner's other important works are *Natur und Geist* (Frankfurt 1857, 3rd ed. Halle 1874) and *Darwinismus und Sozialismus* (Leipsic 1894, 3rd ed. Stuttgart 1910).

SIDNEY HOOK

BUCKET SHOPS. A bucket shop is an organization which poses as a commission brokerage house, dealing either in stocks or in grain and cotton futures, but which does not actually execute the trades that are ostensibly made through it for the account of its customers. If, for example, a customer gives the bucket shop an order to purchase on margin 50 shares of corporation stock, the bucket shop merely makes a book entry indicating that the customer has purchased this amount of stock at a nominal price based on the next transaction on some exchange. When the customer orders the stock sold he is credited with the nominal selling price and his margin deposit is returned to him with an addition or deduction for his profit or loss. If the customer decides instead of selling to pay out the balance of his account and take the stock, the bucket shop must of course buy it for him, taking a profit or loss on any change in price which may have occurred. In effect the bucket shop simply speculates on the opposite side of the market from each of its customers to the extent of the customer's open trades.

There are several advantages which the house derives from bucketing. First, there is a saving in interest. Whereas a commission house expects to make a moderate profit on the difference between the rate it charges customers for loans and

the rate it pays for bank accommodation, a bucket shop can keep the entire amount of interest which it charges all margin buying accounts just as if the orders had actually been executed. Second, a bucket shop saves the expense involved either in maintaining representatives on the floor of an exchange or in payment of commission to exchange members. Its commission rates are ordinarily the same as those of a legitimate house, but the charges are net profit. Third, there is a possibility of profiting by manipulation of purchase and sale prices. A legitimate brokerage house reports to each customer the actual price involved in every trade for his account and is interested in securing for him the most favorable prices possible. The bucket shop reports an arbitrary price, based in theory on the next official quotation after the order is received. This procedure offers the house an opportunity to report as high a price as is plausible. For instance where orders are received by mail it is quite possible to report the highest price on purchases and the lowest price on sales made during the day.

Bucketing, of course, exposes the house to the risk of speculative loss if its customers are predominantly on the right side of the market. When the shop has a considerable number of customers it is to be expected that long and short accounts will to a considerable extent offset one another. In case there is a predominance of long accounts, as is usual, the bucket shop can, of course, eliminate its risks by actual execution of a sufficient number of purchase orders to leave the bucketed trades in balance.

A more roundabout method of bucketing came to public attention as the result of a long series of failures of brokerage houses in the winter of 1921-22. In this method of operation a customer's order was executed in the regular way, either through an exchange or "over the counter." At the same time the house actually made a trade of the same size on its own account, taking the opposite side of the market. For every share its customers were "long" the house was "short," for every share they were short it was long. At the close of each day the purchases and sales were in balance, so that no stock had to be received or delivered and no money had to be borrowed or advanced by the house.

During the protracted period of falling security prices which terminated in the summer of 1921 a large number of concerns employed this system to their very great profit. Because the majority of their customers were committed to

the long side the houses which practised "trading against orders" made money on their own trades, while the low interest rates they charged served to attract a huge clientele. When the market turned upward and the public began to make money such firms failed in great numbers. Investigations usually showed that those of the customers' funds which had not been lost in trading short against the rising market had been wasted or stolen.

The fight against bucket shops is being carried on by public authorities and by the organized exchanges. Several states have enacted laws specifically aimed at bucketing. One of the most effective of these is the Martin Act of New York state, which imposes upon the attorney general the duty of detecting and prosecuting bucket shops. The organized exchanges prohibit their members from doing business with bucket shops and withhold ticker service from suspicious non-member brokerage firms. These measures have not so far succeeded in completely doing away with bucket shops; many of them continue to inflict losses upon the inexperienced speculator of small means and to discredit speculative trading in the eyes of the general public.

BUCKLE, HENRY THOMAS (1821-62), English historian. Buckle's *History of Civilization in England* (2 vols., London 1857-61; new ed. by J. M. Robertson, 1 vol., 1904) is but the introduction to a great work which was cut short by the author's early death. He begins by describing the method of a true inductive science of history, of which his work is to be the first example. Man is wholly a part of that nature about which modern science has discovered so much. The incompetence of historians, their preoccupation with individual biographies, with political and military history, coupled with the lack of adequate statistical materials on past ages, have hitherto prevented history from establishing itself as a true science

with a body of laws. Drawing on his wide reading Buckle by a process of inductive reasoning worked out physical, moral and intellectual laws which he claims are universally valid. Physical laws are of two kinds: those which show the relation between such factors as soil and climate and material wealth; and those which show that where nature is too terrible man's mind is overstimulated, that where nature is too mild man's mind is understimulated, and that only in Europe is the balance reached and man made nature's master. Moral laws are everywhere unchanging and therefore without influence on man's progress. Intellectual laws show that the genuine scientific method, a combination of induction and deduction, has, when allowed free play, guided human beings—or rather certain European races—to more perfect civilization. Buckle then attempts to illustrate these laws from the history of France, Spain and Scotland and concludes therefrom that complete intellectual freedom, with the consequent willingness to doubt and investigate, permits the unimpeded working of the laws, but that the "protective spirit" in art, thought and industry curbs their operation and impedes progress.

Criticism of this system is too easy to be profitable. But in its very inadequacies the *History of Civilisation in England* is one of the most important works in the history of the social sciences. In the first place it was translated into all the important European tongues and widely disseminated (Wallace found it in translation in the huts of Russian peasants). Its brash confidence in progress, its lordly generalizations, its apt detail and its swinging rhetoric, its attacks on conservatism, especially on clerical conservatism, gave it a place superior even to that occupied by Comte, Mill and Spencer in the minds of thousands of obscure, faithful nineteenth century radicals. In the second place it is, by the fact of its great circulation, one of the best possible sources for a study of an important phase of public opinion of the time. For the investigation of the meaning given by even quite ordinary Victorians to such abstractions as "progress," "liberty," "civilization," "protective spirit," it is invaluable. Finally, although Buckle was exceptionally gifted for abstract speculation, his attempt to apply his powers to the stuff of history resulted in so many unresolved difficulties, so many faults of logic, that his work must remain as a warning to all who hope to deal with history as a science.

Buckle scandalized contemporary historians

and perhaps helped to keep them more than ever attached to safe and narrative history. Recent historiography is, however, wholly in sympathy, if not with Buckle's methods, at least with his underlying assumptions as to the nature of history. In particular his emphatic insistence on the study of the masses of men rather than of the exceptional individual has helped to create modern social history.

BUDDHISM

DOCTRINES AND INFLUENCE. Buddhism is a religious system which, since its origin in India in the sixth century B.C., has spread out to nearly all the Asiatic countries and so influenced their peoples that oriental culture in large measure may be called Buddhistic. Its name is derived from an appellation of its founder, "Buddha," or the "Enlightened," who is otherwise known as Gotama, his family name, or Sakya-muni, the sage of the Sakya clan which inhabited a portion of the borderland of the Himalaya range and the valley of the Ganges. The appellation Buddha was one adopted by the founder himself, probably in contradistinction to the other prevailing epithets signifying sage, seer or leader. It expressed a significant characteristic of his leadership: the conviction that a man fully enlightened in the truth of existence, aware of the oneness of all beings, had a mission to lead all fellow beings to a life embodying that truth and therefore to the same dignity of Buddhahood.

The metaphysical conception of the oneness of existence had been developed through many years by the Brahmanic predecessors of Buddha, but its application as a practical social ideal had ever been hampered by the caste system and the sacerdotal authority of the Brahmins, the privileged priestly class of India. This caste monopoly was, at least in theory, broken down by the leadership of Buddha, who had himself belonged to the warrior class but abandoned all the glories and luxuries of an aristocrat for the

sake of his spiritual ideal. When he appeared as the teacher of a new gospel of equality, however, he was not so much an active social reformer as a propounder of the way of purity to be practised by all. His disciples included men and women, princes and outcasts, wealthy and mendicants, scholars and barbers, even sinners and robbers. His ministry and the consequent formation of the community (*sangha*) of his disciples aroused little resistance from the established religions except in a few instances. The *sangha* had become quite a significant force throughout India by the time of his death, about 480 B.C. (the dates of birth and death of Buddha are controversial; most scholars now agree upon c. 560–480 B.C., but in Burma, Siam and Ceylon the dates 623–543 B.C. are generally accepted); in succeeding years its influence spread gradually and steadily beyond the boundaries of India until within ten centuries the Buddhist religion had become the ruling force of nearly the whole of Asia. Even in India, where it disappeared as an active religion about the tenth century A.D., the Buddhist tradition never wholly ceased to influence religious and social life.

Buddhism as a driving force in faith and culture can be understood only after an examination of the spiritual sources of its influence. Perhaps the most important factor in its appeal was the personality of its founder. He exemplified in his own life and stressed in his leadership the fact that worldly glories or wealth have nothing to do with the real value of life; that neither knowledge nor erudition but spiritual insight or “enlightenment” is the key to real bliss; and that fellowship in sympathy and charity is the consummation of self-training. The importance of this doctrine lay in its emphasis not only on the power of personality but also on the equality of every person in respect to the destiny to Buddhahood. Herein lay the kernel of Buddhism as a universal religion, which could not only overshadow the caste system of Brahmanic India but could unite peoples of different races and cultures in one ideal of universal perfection.

The type of personal training advocated by Buddha was also largely responsible for the influence of his doctrines. Asceticism had long been a major force in Indian society. Buddhism took over this ideal, and the methods of Buddhist training were certainly ascetic. Buddha himself, however, went through them as a middle way between pleasure and self-torture, with the aim of self-purification leading to the

denial of selfish motives and to the realization of the oneness of existence in the spirit and life. Although some forms of Buddhism developed extreme ascetic practises, Buddha personally emphasized moderation. Buddhist training bore its best fruits in the development of strong personalities and in a widespread and effective stimulation of charity and social service. Indeed the Buddhist training resulted in something like a harmonious combination of the spiritual exercise of the Jesuits, the charity of the Franciscans and the social service of the Benedictine monks.

The doctrinal basis of Buddhist influence is contained in the teaching of karma and dhatu, which may be considered the fundamental ethical and social ideas of Buddhism. The metaphysical basis of these ideas may be found in the Brahmanic *Upanishads*, but it remained for Buddhism to develop their social implications. The central concept of karma is that of deeds and retributions lasting through lives: the present life is the result of the past karma, the future of the present; life is a continuity surpassing the reach of memories and stretching beyond the grave, a link of changing and moving forces of deeds and retributions. This continuity is not limited to the individual life but applies also to grouping of beings, dhatu. Just as one individual life constitutes a phase of the long series of deeds and retributions, so the nature of a group is the manifestation of a common karma as well as the determining force for the beings born into the group. And as there are infinite varieties of karma, so are the kinds of dhatu numberless, ranging from the larger realms of existence, such as the heavenly worlds and the purgatorial circles, the races of animals and mankind, to the groupings of people according to locality, community, class, guild, family and even to the links binding loving couples or hated enemies. Not only weal or woe, love or hatred in the individual life, but the growth or decay of races, the rise or decline of kingdoms and even of world systems—every movement of life is a phase of the large cosmic movement of the forces called karma and dhatu.

These ideas had a variety of social manifestations. They led people to see the extent and meaning of life even to the overcoming of its individual limitations. Karma comprises thought, speech and bodily acts, all of which must be purified to assure escape from the entanglements of vicious karma. But since mental acts—ideas, feelings, intentions—are chiefly emphasized, spiritual exercise and training of

the will assumed great importance. Appealing to the sentimental life, the idea of karma refined it by arousing a delicate sense of sympathy in every movement of feeling and emotion. Herein lay the basis of one of the characteristic features of Buddhist charity, its close association with a sense of compassion or commiseration (*metta-karuna*). In practise Buddhism encouraged social service of many kinds as part of the obligation of every Buddhist to his fellow beings, not only because of the links of karma and dhatu but in order that these fellow beings might be led to Buddhahood, or "Supreme Enlightenment." On the other hand it must be realized that the influence of the doctrine of karma was stronger in affecting sentiment than in leading to active work; it is also true that in many cases the doctrine led to an easy submission to the irrevocable. Thus western critics of Buddhism are not entirely mistaken when they criticize it as fatalistic and pessimistic, but such criticism fails entirely to explain the vitality and quickening influence of Buddhism in its period of growth.

One factor in this influence was the vitality of the sense of community given by Buddhism and developed from certain aspects of the conception of dhatu. The dhatu may be a solidarity based either on avaricious intentions or on mutual service and loyalty. Since most worldly groups are products of custom and instinct, there is great need for the deliberate formation of others on the basis of reason and high ideals. The Buddhist *sangha* as the most important of such groups is called the "harvest-field of merit" (*pumma-khetta*); and it was in the formation of *sangha* that the fundamental ideas of Buddhist faith found actual embodiment. The *sangha* was a community for the mutual enhancement of meritorious deeds. Not only did its regular members, the monks and nuns, owe one another help and emulation; these monastic members contributed to the community the "gift of truth," i.e. teaching, while the lay followers, particularly those who were organized in a kind of tertiary order, were responsible for the "gift of provision." Thus the pervading idea of Buddhist life was that of mutual indebtedness, religious, moral and economic, not limited to the visible community but in ideal communion extended to all the saints of the past and future, visible and invisible beings, all destined to become enlightened and finally to attain Buddhahood. It was the actual community that proved effective in enforcing discipline, in organizing social and missionary work, in perpetuating

ideals and traditions, while the ideal extension of the fellowship inspired all Buddhists to a sense of union transcending race, class, country or time. This idea of invisible communion in enabling Buddhism to adopt the divinities of other religions made easier the spread of the Buddhist faith; in keeping alive the sense of communion with the intangible genii of nature it both enhanced the poetic imagination and induced compromise with animistic beliefs.

A central tenet of Buddhism is the universal application of its "Three Gems": the "Person" of Buddha, the "Truth" revealed by him and the "Community" of his followers. The missionary spirit of Buddhism was originated by the founder himself. Buddhists call the first preaching by Buddha "Turning the Wheel of Truth,"—the wheel which goes unimpeded everywhere, the truth which is destined to lead all beings to Buddhahood. According to tradition Buddha hesitated to reveal his spiritual vision because he thought it too hard for common mortals to grasp. The overcoming of this hesitancy implied his determination to open wide the "Gateway of Immortality" to all; and the first sermon given at Benares about 525 B.C. together with the missionary charge delivered to his disciples heralded the opening of a great missionary movement which was destined to cover the whole of Asia. The fifty years of his ministry were spent in journeys of preaching, consoling, admonishing, throughout the valley of the Ganges. Many of his disciples followed his example, one of them starting a foreign mission among the savage Sina tribes beyond the Indus. The missionary spirit of Buddha was expressed by his adoption of the appellation Tathagata, meaning Truth-winner and Truth-revealer.

In his lifetime Buddha not only visited pest stricken regions and penetrated into warring countries, but he also caused his rich followers to establish hospitals and asylums, to institute famine relief and travelers' aid; even the poor shared in the giving of personal service. There are many legends illustrating his effectiveness in overcoming caste distinction and in stimulating sympathy and charity; even if these have no basis in fact they show the ideal aims of Buddhism in the period of its growth. More solid historical data as to its development are found in the edicts of King Asoka inscribed on rocks and preserved nearly intact, wherein Buddhist works of social service and the establishment of foreign missions are unmistakably recorded. Asoka's reign (c. 269–c. 232 B.C.) marks the high point of

Buddhist influence in India and it was due to his zeal that Buddhist missionaries traversed the continents and seas. Within a few centuries most of southern Asia had come under Buddhist influence, while Central Asia and the Far East were brought into the circle during the first five centuries of the Christian era. Introduced into China in the first century A.D., it spread into Korea in the fourth century, thence into Japan in the sixth and southward from China into Annam about the tenth century A.D.

The spread of Buddhism was notable for the number of strong personalities it engendered. Buddhist missions everywhere supported and stimulated a cultural vitality that led to the development not only of saints and ascetics, missionaries and social workers, but also of statesmen and physicians, artists and poets. Of many we have historical records, others left works of art or literature, while some survive only in deified form. Indeed largely to Buddhist inspiration is to be credited the galaxy of great men and some women adorning the histories of the Asiatic peoples in the thirteen centuries from 500 B.C. to 800 A.D.

The civilizing effects of Buddhist influence are no less marked. In addition to its rich heritage of Brahmanic culture Buddhism absorbed a certain amount of Greek culture, which had early implanted itself in the northwest of India. After a further contact with Persian influences Buddhism civilized the nomad peoples of Central Asia. Under its inspiration scripts and systems of writing were adopted, worship was adorned by art and the social life was largely molded by its ideals. No more vivid testimonies to the civilizing influence of Buddhism are seen than in the relics unearthed from the buried cities of Central Asia. But of more far reaching importance was its influence upon Chinese culture, which was destined to mold the civilizations of Korea, Japan, Tibet and Indo-China. Buddhist influence also progressed southward even as far as the Melanesian Islands, where, however, the Brahmanic heritage was more predominant than in the north.

Though not entirely homogeneous the whole of Asiatic Buddhdom during the first six or seven centuries of the Christian era formed an area of one pervading culture in which Buddhism was definitely the inspiring and integrating power. This oriental civilization, however, could not resist the forces of disintegration. The effects of political separation, the migrations of the nomad tribes and the division into schools

and sects were brought to a climax by the Mohammedan invasions and the Brahmanic revival and finally broke down the solidarity and the common culture of Buddhdom. In India Buddhism has been of minor importance since the twelfth century A.D.; in other countries it has taken on national characteristics. But whatever its present position or future fate no one can ignore the fact that Buddhism was once an integrating and civilizing force throughout the whole of the Orient.

The weakness and the strength of Buddhism were alike due in large part to the tendency to compromise which characterized Buddhist propaganda. Buddhism has always worked as a conciliatory force, only in the most exceptional instances fostering the development of a combative attitude. Thus there was no aggressive hostility manifested by Buddhism in its contacts with Zoroastrianism, Manichaeism, Nestorian Christianity, Confucianism, Taoism or even with Brahmanism, in protest against which it developed. Rather in every case a certain amount of mutual influence resulted from the contact; this was equally true of the relationship with lower forms of religion among less advanced peoples. Wherever Buddhist propaganda proceeded it enfolded the native deities within its own pantheon and made more or less of a compromise with the original beliefs and practices. In many cases Buddhist influence elevated and purified the autochthonous heritage, especially during the first stages of proselytism when inspiration was fresh; but the compromise often involved degeneration in Buddhism itself. Yet no one can conclude that even such corrupted forms of Buddhism as Shamanism and Lamaism will never renew their vitality. In fact signs of reawakening are visible in most of the Buddhist countries today, and Buddhism may well claim the serious consideration of the whole world.

M. ANESAKI

INSTITUTIONAL ORGANIZATION. The basis of Buddhist organization is the monastic system and the value placed upon monasticism as a way of life. In every country this system developed its own peculiar characteristics, in some cases achieving great strength. In Tibet, for instance, Buddhist monks became stronger than the secular party and the Dalai Lama is head of the state as well as of the Buddhist order. In medieval Japan the great monasteries threatened to become the chief military as well as the chief political power; only the destruction in the six-

teenth century of some of the largest establishments restored power to secular groups.

Monasticism as the organizational basis of Buddhism derived its strength from its place in Buddhist doctrine. For while Buddhism does not deny to the layman the possibility of achieving happiness, its ideal is the monastic and contemplative life and the support of the monasteries is a duty of every lay member of the faith. The strength of this tradition has assured the spread of the monastic system without the development of central agencies and with full freedom for local variations of structure and opinion.

This emphasis on the importance of the monastic way of life Buddhism inherited from Vedism and Brahmanism. The earliest Indian reference to the religious solitary is in the *Rig-veda* (x. 136) where the *muni*, or monk, described as clad in a faded yellow robe, is shown obtaining power to pass through the air and enter the realm of the gods. Here is an indication, about 1000 B.C., of the root from which developed that yellow robed order, the most far flung and picturesque in the world; and here too can be traced the beginnings of the theory which plays a considerable part in popular Buddhism, that *tapas* or austerity gives men magic power. From this root sprang the *paribhajakas*, or friars who, usually under a chosen leader, wandered from place to place living on alms and only during the wet season went into retreat in order to avoid harming the insect life with which the earth teems during the torrential rains in India.

The Buddha was the leader of such a group. This order, or *sangha*, began very simply. The simple words, "Ehi bikkhu" ("Come, be my monk"), with which he called men of all social ranks to join him were gradually replaced by the elaborate *upasampada*, or ordination ceremony, with its declaration of faith in the "Three Gems"—Buddha, Teaching and Order—confession of sin, tonsure and other requirements. But in two collections of psalms by early followers which have come down to us there is ample evidence of the democracy and the spirit of enthusiasm in the first little group. It seems clear too that women, although with some hesitation, were admitted as nuns. The great mass of people, however, were called to a different life, yet one which centered about the Teacher. To the inner circle he offered the Middle Path which leads to *Nibbana*; to the lay people he promised rebirth in a heaven through devotion to his person. This division into monks and

nuns on the one hand and lay people on the other led naturally to a division of function: the monks being "the harvest-field of merit" and the laity winning merit and progress to some heaven by gifts of food, clothes and buildings. As the friars needed a place for meditation, kings and merchants presented them with parks and monasteries; thus there came into existence the *vihara*, or dwelling place, and the *chaitya*, or shrine—each to develop from simplicity to great complexity. The bas reliefs of Barhut supplement the texts in illustrating this development. They show, for instance, a king building a monastery and a rich merchant buying a park for the monks. The edicts of Asoka (third century B.C.) indicate that the great emperor was not only their patron but gave them advice as to what they should read and warned them against the dangers of schism.

In the Bhabra Edict Asoka mentions a *vinaya*, or code of discipline. The *patimokkha* (at first a way of conduct of the sect, later a ritual of the order) seems to have been the core of such a code, to which were added rules as occasion arose. The whole elaborate system can no more be traced to the founder than can the monastic rules of Christendom be traced back to Jesus, but it seems clear that the Buddha had much more definitely in mind than did the founder of Christianity an order of monks whose aim was that experience of transcendental truth which he called *Nibbana*, and that the teaching activities of the monks, like all other things, were subordinated to this; whereas the first group of Christian disciples were sent out to preach a new social order based upon a new vision of the divine nature. It is also clear that both groups became increasingly more monastic and ascetic than either founder intended. Thus the followers of Buddhism began to meditate upon skulls and to visit burial grounds, as the followers of Jesus began to turn away from the married life and to attach an exaggerated importance to penance and suffering. In Buddhism there was, about 100 A.D., a new orientation toward a more emotional morality, a multiplication of personal deities and a higher valuation of service to one's fellows rather than the achievement of personal merit. A similar transformation of Brahmanism, visible in the *Bhagavadgita*, was occurring at about the same time. The new movement in Buddhism called itself Mahayana (the great way), and the older ascetic tradition Hinayana (the little way). Neither group supplanted the other, but it was the Mahayana movement with

its appeal to the masses and its social emphasis, its more elaborate ritual and also its infiltration of popular superstitions and practise of magic that colored Buddhism in its spread throughout the Orient. Both schools have a canon, and Tibetan Buddhism, born of the blending of the Mahayana with Tantric Hinduism, has its own canon and commentaries.

With a developing Buddhism there arose a hierarchy within the monastic system. The first step in this process may be said to have occurred when the primitive *stupa* (burial mound to mark some sacred spot or enshrine some relic) was turned into an altar and the monk into a priest. The simple dirge:

Sabba dukkha all is sorrowful
Sabba anicca all is transient

gradually passed into an elaborate "three-part service" with chant, reading and sermon, and the head of the *vihara* became a great abbot honored by kings; the *chaitya* became an elaborate cathedral. These developments were complete within about five centuries of Gotama's death, although he is pictured emphatically insisting, as he dies, that his followers are not to appoint a successor as their chief and even refusing to make rules for their guidance. Other texts, however, show him doing both these things and in the growth of this later tradition may be seen both the process by which the elaboration of the *sangha* is accomplished and the growing veneration in which the founder is held until he becomes "God over the Gods" and the eternal *dharma*, law, embodied in time. The early distinction between the novice, *samanera*, and the elder, *thera*, developed into a hierarchy of four orders with a head abbot. It has been to the detriment of Buddhism that its monks have frequently become too powerful and that, as in Christendom, missionaries have given place to leaders or armed knights and retainers. But in each Buddhist country there is a strict or reformed sect claiming to go back to the discipline of the early *sangha*.

Buddhist monasticism has tended to resist centralized authority. The Meditative sect (*Chan* in China, *Zen* in Japan) claims a patriarchal succession with the great missionary Bodhidharma (sixth century A.D.) as twenty-eighth in succession from Kasyapa, appointed by the Buddha; but this is unhistorical and at best embodies the fact of a great succession of authoritative mystics. In many monasteries the abbot is elected for a three-year period; and each abbey foundation is a law to itself. Although Dengyo and his

contemporary Kobo in the eighth and ninth centuries and Nichiren in the thirteenth sought to establish a national church, even Japan with its strong centralized government has preferred denominational allegiance. In the Shinshu sect with married priests and hereditary abbot it seems to approach greater unity, but even this sect is no more a national church than that of the Methodists of the United States, which it resembles in numbers, pietism and wealth. Buddhism, the religion of mystic enlightenment, believes in the authority of the saint rather than in that of the ecclesiastic, and when a great leader arises he is called the "Great Teacher." The monks are still in theory mendicants vowed to poverty and "clad in rags." The "rags" may be priceless brocades and the mendicant a prince—as in Christendom.

As Buddhism spread throughout the Orient, this monastic order established itself with varying strength in different countries. A typical Buddhist kingdom is that of Siam, in which the order is mildly ascetic, the dominant although not the only religion, given its place of honor by a devout people and a loyal king and in which the king's brother is Sangharaja, chief of the order. Very similar is its place in Burma and Ceylon, where its strength is shown by such magnificent monuments as the Shwe Dagon and the parks and buildings of Anuradhapura and by the fact that today it owns as much as one third of the arable land of Ceylon, and has two pagodas to every village in Burma. In China Buddhism is but one of several officially recognized religions; but here too it has not failed to gain lands and wealth.

With the rise of nationalism in modern Ceylon and Burma the numbers and prestige of the monks have increased; world weariness in China has again filled the monasteries; and throughout Buddhist countries, perhaps most noticeably in Siam, there are rising standards of scholarship among the Bhikkhus. Education has always been a Buddhist activity; the hold upon the young which this gives the monks is not being relaxed; in some centers it has been tightened by imitation of western Christian methods such as religious education, clubs and social service work.

In return for the "gift of teaching" the order continues to ask the alms of the faithful. These are usually given cheerfully by the women; but the men realize that with one son in every family a monk, as in Tibet, or with the endless building of pagodas, as in Burma, the Yellow Robe is at times a very burdensome economic liability.

Young China is making deliberate war on the monks. Modern Japan, on the other hand, looks kindly upon the order, which is not only her ally in the "pacification of Korea" but with the enhancement of land values in Japanese cities has become an economic power. There were in 1918 in Japan 71,681 temples, 117,982 priests and 5023 nuns in a population of 50,000,000. This may be compared with the figures for Ceylon with its 2,750,000 Buddhists and its 7700 monks in a total population of 5,000,000; for Burma with 75,000 monks in 10,500,000; for Siam with 93,000 monks in a population of 8,500,000; and for Tibet with 700,000 lamas in 3,500,000. Figures in China are harder to estimate as Chinese Buddhists can usually be also reckoned as Confucianists and Taoists, but there are nearly a million monks in Chinese Buddhist monasteries.

Much smaller in numbers but still influential in their austerity are the hermits. "Wander solitary as the elephant," say many passages of the Buddhist books—and these men, immured in some cave in the Himalayas or alone in the jungles of Burma, have their appeal to many to whom the sanity of Buddha's Middle Path seems too mild and reasonable. These extreme ascetics keep alive the dim hope of *Nibbana*, now accepted in all Buddhist lands as unattainable in this age. The otherworldly hermit remains to reproach the worldly monk or layman. This example cannot destroy but may spiritualize the organization of Buddhist monasticism.

BUDÉ, GUILLAUME (1468-1540), French jurist and humanist. Budé was secretary to Francis I and later *maître des requêtes*. He was a student of archaeology, translated the works of Greek authors and wrote several treatises on linguistics. He was the first to employ philology in the elucidation of Roman legal texts, striving thus to avoid the errors of the mediaeval jurists, Glossators and Bartolists in their commentaries on the *Corpus juris civilis*. In his *Annotations in Pandectas* (1508) he points out numerous copyists' mistakes and proposes judicious corrections. He was the precursor of the modern Romanists, who from the time of Cujas have been concerned with textual criticism and with the study of Roman law as history rather than as contemporary legislation. This method had as its ultimate result the weakening of the influence of the *Corpus juris* on the political thought of the time.

Budé's political ideas are to be found in his *De l'institution du prince* (1516), which already foreshadows the absolute character of the French monarchy. According to Budé it is wrong for the king to disregard his own ordinances but he is not accountable if he does so. The treatise *De asse et partibus* (1515), although it is devoted nominally only to the Roman monetary system, deals in reality with Greek as well as Roman monetary problems, such as the basis of division, the variation in weights, the relative value of gold and silver and the purchasing power of precious metals. It is the oldest French study in economic history and created a profound impression on its appearance.

BUDGET is a term derived from the old English word *bougette*, the sack or pouch from which the chancellor of the exchequer extracted his

papers in presenting to Parliament the government's financial program for the ensuing fiscal year. It has been defined by René Stourm as the "document containing a preliminary approved plan of public revenues and expenditures."

While this is a satisfactory description of the budget document, it fails to bring out the real significance of the budget system, which is to provide for the orderly administration of the financial affairs of a government. The conduct of such affairs involves a continuous chain of operations, the several links of which are: estimates of revenue and expenditure needs, revenue and appropriation acts, accounts, audit and reports. An estimate is first made of the expenditures that will be required for the proper conduct of governmental affairs during a fixed period, usually one year, together with proposals for raising the money to meet these expenditures. On the basis of this estimate revenue and appropriation acts are passed giving legal authority for the action determined upon. Following this the operating services open revenue and appropriation accounts corresponding to the items of the revenue and appropriation acts and proceed to expend the money so voted. The data recorded in these accounts are examined by the auditing and accounting department to insure their accuracy, to see that they correspond to the real facts and represent a full compliance with all provisions of law. The information furnished by these accounts is then summarized and given publicity in the form of reports. Finally on the basis of these data new estimates for the next year are made and the circuit is begun again. In this chain of operations the budget is the instrument through which the several operations are correlated, compared and examined at one and the same time. The budget is thus more than a mere estimate of revenues and expenditures. It is, or should be, a report, an estimate and a proposal: the document through which the chief executive, as the authority responsible for the actual conduct of governmental affairs, presents to the fund raising and fund granting authority a full report regarding the manner in which he and his subordinates have administered affairs during the last completed year, and a statement of the present condition of the public treasury. On the basis of such information the executive sets forth his program of work for the coming year, with proposals as to the financing of such work.

The most important feature of a budget is comprehensiveness. It must assemble in one

consolidated statement all facts regarding expenditures and revenues, past and prospective, the actual financial condition of the treasury and the condition of the treasury as it will be if the proposals contained in the budget are put into execution. These facts, moreover, must be presented by means of balanced statements, so that the relations between past action and proposals for the future, between revenues and expenditures and between resources and obligations may be clearly seen. Thus the budget presents the whole problem of financing the government at one time and focuses legislative attention on the relation of the total expenditure needs to the total prospective revenues.

The fact that budgets must be made in advance of the period in which they are to operate involves some difficulties. Exigencies unforeseen when the estimates were drawn up necessitate additional expenditure, often upsetting the balance achieved by the budget. Moreover additional appropriations, while sometimes unavoidable, make possible the kind of undesirable expenditure which it is in part the object of the budget to prevent. Administrations may even resort to the trick of submitting to the legislature a budget which will easily win approval and of trying later to secure additional appropriations on the grounds of emergency, thus relying on the decreased vigilance of the legislature and sometimes on the *fait accompli* of administrative commitments to win approval for expenditures which might otherwise have been refused. Another manner of evading the budget is the transfer by operating authorities of funds from one appropriation account to another, followed by an appeal to the legislature to grant additional moneys to cover the indispensable operations of the account tapped. Most budget systems now forbid the practise of transfer and provide for control of all additional appropriations, with a view to making them undergo the ordinary budgetary procedure and thereby maintaining the balance of revenue and expenditures.

Extraordinary budgets have at times been passed in addition to the main ordinary budget, chiefly to finance war or war preparations or for such elaborate expenditures as were necessitated by the railroad building programs of European governments. These expenditures are covered by loans, and the cost of amortization is shifted to future years or generations by omitting the items from the ordinary budget. Whatever justification this procedure may have in cases of dire necessity it has been abused by classifying

as extraordinary items which are really not extraordinary, in order to create an impression of economy by not overloading the ordinary budget. In most countries this practise has in recent years been practically discontinued. Similarly the practise of omitting from the main budget activities expected eventually to yield comparable return (e.g. industrial bounties or subsidies) and of covering the expenditure by loans for the repayment of which no provision is made in the budget has proved unfortunate in numerous cases when the expected revenue has failed to materialize. Such operations can be properly controlled only by means of the ordinary budget.

Other items which escape accounting in the ordinary budget are expenditures connected with revenue producing services, of which the postal service and railroads are typical. For administrative reasons such services are generally autonomous subsidiary corporations, and separate budgets cover the finances of each; these are tied into the main budget only by noting the net result, profit or loss, of the whole year's operations.

The conception of the budget as the central instrument of financial direction and control is a comparatively recent development. In England and on the continent the use of the budget as a financial program, emanating from the executive and submitted to the representative assembly for approval, was chiefly the outgrowth of the demand that no financial burden be imposed upon the people without their consent expressed through their representative assembly. In England the right of such financial control is very old, having been specifically extracted from both King John and Edward I. It was violated occasionally by the Tudors and was a crucial point in the struggle between Parliament and the Stuart kings culminating in the civil war of 1642-49 and the revolution of 1688. The accession of William and Mary and the passage of the Bill of Rights settled finally the exclusive right of Parliament to levy taxes and to authorize expenditures. Similar struggles were experienced in America and France, also culminating in revolution, and after 1789 the principle of parliamentary control of finances spread over Europe. Although *Voranschlagen* were known as early as the fifteenth century in Prussia and were made public as early as 1688 complete budgets did not come into existence in Germany until the early nineteenth century constitutions of Bavaria, Saxony, Württemberg, Hessen and

Baden confirmed the ancient legislative right of consent to taxation. The main revenue and expenditure figures were made public in Prussia in 1821 to bolster up public credit, and constitutional rule brought a *Staatshaushalt-Etat* to that country in 1850; but as late as 1862 Bismarck, unable to agree with the Landtag on finances, could still assume for the royal administration the power to act alone lest the inability to reach a compromise stop the life of the state. Austria adopted a budgetary system in 1766, but full legislative control of finances did not come until after the fall of the Hapsburgs in 1919.

In these struggles interest centered on revenue rather than on expenditure. The budget as first used was little more than the means of controlling the raising of revenue from the people, and comparatively slight attempt was made to set up any control over the expenditure of the funds. Gradually, however, the principle was developed that the popular assembly should control not only the raising of revenues but the purposes to which such revenues should be devoted. Viewed in this broader aspect the use of the budget may be said to have had its beginning in England about the time of the revolution of 1688, and in France and other countries of Europe at the time of the French Revolution of 1789.

Since this principle of securing from the executive a formulated financial and administrative program had become firmly established in all the leading countries of Europe early in the nineteenth century and represented such a manifestly desirable device, it is remarkable that it was not adopted in the United States until the beginning of the twentieth century. Prior to that time little or no attempt had been made to distinguish between the two operations of formulating and taking action upon a financial program; both were considered as parts of the function of the legislative branch. Although the several administrative services were generally required to submit to the legislature so-called estimates of their expenditure needs, these represented merely individual requests for funds. The essence of a budget system, that is, a program proposed by the chief executive in which there is a balancing of the two sides of the account with recommendations regarding both expenditures and the means of financing such outlay, was wholly lacking.

The first move to correct this condition of affairs was made in municipal government. In the efforts to improve municipal administration

special attention was given to the demand that municipalities put the administration of their finances upon a budgetary basis. In the model municipal corporation act, drafted under the auspices of the National Municipal League in 1899, a section was inserted which provided that: "it shall be the duty of the Mayor . . . in each year to submit to the Council the annual budget of current expenses of the city, any item in which may be reduced or omitted by the Council; but that the Council shall not increase any item in nor the total of said budget." This provision, though a step in the right direction, indicates that at that time there was no clear conception of the function of a budget. It does not require the submission of recommendations regarding the means of financing proposed expenditures, or a balancing of income with expenditures to show the effect of the proposed expenditure program on the financial condition of the government, or a comparison of proposed with past expenditures so that the purport of the program may clearly be seen. This provision, however, marks the beginning of an increasing appreciation of the proper nature and function of a budget and a steady progress in the adoption of proper budgetary systems by municipal governments in the United States.

From the municipalities the movement for the adoption of a budget system passed over to the states. Beginning with California and Wisconsin in 1911 and Massachusetts in 1912 practically every state of the union has now made some provision for the formulation and use of a budget. The movement to establish a budgetary basis for the national government received its impetus from the recommendations of the President's Commission on Economy and Efficiency, created in 1910 by President Taft. This commission prepared two reports on the subject which had great effect in bringing to the attention of the public the importance of budgetary reform, not only in the case of the national government but in that of all government bodies.

The work thus inaugurated was taken up by the Institute for Government Research, created in 1916, which prepared and secured the adoption by Congress on June 10, 1921, of a bill providing for a budget system. At the same time the two houses of Congress revised their rules of procedure governing the handling of appropriation measures so as to bring them into harmony with the new system thus created. This act, known as the "Budget and Accounting Act,

1921," together with the amendment of the rules just cited, provides for what is probably the most complete budgetary system existing in the United States, if not in the world.

First and foremost it vests in the president the sole responsibility for requesting the grant of funds by Congress. Annually he must submit to a regular session of Congress a document to be known as a budget, in which shall be set forth in detail: first, the condition of the Treasury at the end of the last completed fiscal year, the estimated condition of the Treasury at the end of the year in progress and the estimated condition of the Treasury at the end of the ensuing year if the financial proposals contained in the budget are adopted; second, the revenues and expenditures of the government during the last completed fiscal year and the estimated revenues and expenditures during the year in progress; third, the provisions which in his opinion should be made for meeting the revenue and expenditure needs of the government during the year to ensue; and fourth, such other financial statements and data as he considers necessary or desirable in order that Congress may have before it all the information required to determine the administrative and financial policies of the government in the future. To make this responsibility of the president still more definite the act further provides that no estimate or request for an appropriation or the increase of an estimate or any recommendation as to how the revenue needs of the government shall be met shall be submitted to Congress, or any of its committees, by any administrative officer unless at the special request of Congress or one of its houses.

A second important feature lies in the fact that the president is given an organ of general administration through which he can meet this added responsibility. This organ, known as the Bureau of the Budget, which is located in the Treasury Department but actually functions as an independent service directly attached to the office of the president, has as its primary function the duty of receiving, compiling and criticizing estimates of expenditure needs as they emanate from the spending services. On the basis of the information thus compiled for him the president determines the recommendations that he will submit to Congress in his budget. It is, furthermore, the duty of the bureau "to make a detailed study of the departments and establishments for the purpose of enabling the President to determine what

changes, with a view to securing greater economy and efficiency in the conduct of the public service, should be made in (1) the existing organization, activities and methods of business of such departments or establishments, (2) the appropriations therefor, (3) the assignment of particular activities to particular services, or (4) the regrouping of services." The bureau thus has the continuing task of informing itself regarding the organization and operation of the government in order that it may consider intelligently requests of the operating services for funds and recommend to the president action that will put the government upon a more economic and efficient basis.

The passage of this act represented but part of the action required in order to put the administration of the financial affairs of the national government upon a proper budgetary basis. The law would largely have failed to accomplish its purpose had it not been accompanied by an equally revolutionary change in the method of handling financial proposals as provided for by the rules of the two houses of Congress. This change did away with the old vicious system under which the expenditure needs of the government were considered by nine different legislative committees, each working independently of the other and without reference to any general financial program. Thenceforth all jurisdiction over expenditure was vested in a single committee of appropriations in each house. At the same time the form of the appropriation bills was radically changed so as to bring together all the items of appropriation pertaining to the several departments, bureaus and other operating units of the government, thus securing a centralization of responsibility and an orderly arrangement of items for consideration of financial proposals similar to that which had been brought about in respect to their formulation by the budget act.

The new system thus established does much more than merely provide for an improved technique in the formulation and consideration of financial proposals. It has modified the whole system of national administration. Indeed it may be said to have affected profoundly the political system itself. It has brought about a greater change in the character of the office of the president than any which has occurred since the first organization of the government. It has made the president the working head of the administration in fact as well as in name. The budget serves as his plan of operations, determining

what and how work shall be done and by which arm of the operating services; as such it is comparable to the report of the general manager of a business house to his board of directors. It has radically altered the relations between the president and Congress on the one hand and between the president and the administrative departments and establishments on the other. In the purely administrative field it has changed a condition of affairs in which the individual services largely went their own ways, considered their own interests and paid little attention to general needs, to one in which they are subject to that measure of central direction, supervision and control that is essential to a subordination of special to general interests, a coordination of efforts and a uniformity in procedure that are imperative if efficiency and economy in operation are to be secured.

The budget system of the United States government has profoundly influenced budgetary procedure in the states and their political subdivisions. The systems of the states, however, vary widely in character. Their most fundamental differences appear in the selection of the organ or agency that shall be responsible for the formulation of the budget. Those states which have gone the farthest in the way of reorganizing their administrative branches by grouping their services in departments have tended to follow the federal budget system of placing responsibility for the formulation of the budget directly upon the governor, and giving to him an agency through which he may meet this responsibility. Some states have entrusted the making of the budget to an ex officio administrative board and others to a board on which members of the two houses of the state legislature are represented. These systems are undergoing constant modification, the trend being to bring them more and more into harmony with the federal system.

The most recent development in the movement for budgetary reform in the United States is toward strengthening the power of the chief executive so that he may control the execution of the budget after it, or rather the appropriation acts based upon it, have been enacted. This takes the form of requiring the approval of the chief executive or some central agency acting for him before contracts or other obligations may be entered into or new activities undertaken, and in giving to the chief executive or his central agency the power to prescribe systems of business procedure. The tendency is, therefore, to

make the chief executive increasingly responsible not only for formulating a budget but for its effective execution.

The American federal system is strictly analogous to that of England where the formulation of the budget is concerned, although the American budget document itself is far superior in its technical arrangement and presentation of data to the English budget. The two systems are, however, radically different in respect to the principles governing the handling of the budget by the legislative branch. In England, as a result of the Parliament Act of 1911, the upper house has no power to modify the budget except when the lower house is willing to accept such modification. Furthermore the rules of procedure of the House of Commons provide that no proposal for the expenditure of funds will be considered unless it originates with the ministry; nor will any motion to increase a grant requested by the ministry be entertained. The powers of the House are thus restricted to the reduction of appropriations as proposed by the ministry and to the general consideration and criticism of such proposals. Even the power to reduce is theoretical rather than actual, since the ministry, with its parliamentary majority, can usually defeat such a motion. The result is that in England the executive formulates as well as determines the action upon the budget. As a consequence of this the consideration of the budget in Parliament tends to be perfunctory, and criticism relates mainly to matters of policy rather than to the technical expenditure needs of the government. Some five sixths of the revenue and six sevenths of the expenditures are even fixed by continuous law and do not go through the ordinary budgetary process. This has been the subject of considerable complaint in England, many critics arguing that in effect the submission of estimates never allows direct control over expenditure proposals, and that many estimates in which changes might have been justified emerge from the parliamentary process untouched.

In the United States, Congress retains full power to modify budgetary proposals, a power that can be and is exercised by both houses. For this reason the work of considering and taking action upon the budget constitutes one of the most important tasks of Congress. Elaborate hearings are held by the Committee on Appropriations of the House, and to a less extent by the Committee on Ways and Means of the Senate, for the purpose of determining the justification

for the grant of funds requested; and amendments providing for an increase as well as a decrease in appropriations are made while the appropriation bills are under consideration on the floor of the two houses. Differences between the houses are adjusted through a conference committee.

Thus in American requests for funds are considered by both an executive agency (Bureau of the Budget) and a legislative agency (Committee on Appropriations), while in England only the Treasury has power to give requests effective consideration. The American system has proved as satisfactory as the English system in keeping down appropriations (during the seven years that the system has been in force no instance has occurred in which Congress has appropriated a larger total than that asked for by the president); and in addition to eliminating the evils of legislative initiative in making estimates it retains the advantage of effectual legislative consideration of executive proposals. The two systems, it should be noted, are in strict conformity with the political systems of which they are a part. The English principle of responsible government requires that the ministry's will shall prevail in respect to financial as well as other legislative proposals; while the American principle of the separation of powers requires that the final determination shall rest with the legislative branch.

In France each minister prepares an estimate for his department. The minister of finance summarizes them, adds an estimate of revenues drawn up solely by his department and drafts the budget message. Constitutionally his authority is no greater than that of any other minister, and he can do little to control their estimates other than make general recommendations of economy. The distrust of the executive, characteristic of the French legislature, is expressed in budgetary procedure by the reservation of full rights to amend ministerial estimates up or down. Until 1900 French deputies could introduce amendments on their own initiative and even today this power has not been entirely removed. Through its power of initiating the budget the lower house dominates the upper in France, the latter often being deprived of any real opportunity to examine the budget because of the late date on which it is passed by the Chamber.

The German budget system, as laid down by the Weimar constitution, contains a number of unusual features. The minister of finance en-

joys special powers in drawing up estimates, and when he has the chancellor's support he can veto requests of his other colleagues. He thus acts as a sort of controller general. The upper house exercises more authority than its counterpart in most other countries, and when it has the support of the president of the republic it can override the lower house. The special powers which under Article 48 of the Weimar constitution may be assumed by the president in "emergency" situations were recently (July, 1930) used to dissolve a Reichstag which had failed to reach an agreement on the budget. The budget systems of colonial dependencies are in various stages of evolution in respect to both the separation from the budget of the homeland and the principle of legislative control. Perhaps the chief indication that they have outgrown colonial status is that the British self-governing dominions make and execute their own budgets. Whatever the legal fiction may be, real colonial budgets imply the dominant control of the home government. In India the budget is that of "the Governor General in Council," and although the Indian legislature discusses it, the lower and relatively popular house has no control over it. Even the Governor's Council, in which officials and nominated members are a majority, must bow to the will of the chief executive, who is responsible only to the home government. Both the Philippines and Porto Rico have budgets of their own; but again the colonial legislature is subject to the wishes of the executive, especially since each statute provides for the renewal of the current budget in case of failure to pass a new one. Thus the administration, controlled by the home government, enjoys a supreme advantage in negotiating budgetary legislation with the colonial legislature.

BUDIN, PIERRE (1846-1907), reformer of obstetrical practise and education in France, creator of infant welfare centers. As a young obstetrician in the Paris hospitals he succeeded in gaining for his colleagues a rank and prestige equal to that of other physicians and surgeons. In later years, as professor of obstetrics, president of the Société Française Obstétrique and editor of *L'obstétrique*, he contributed to the safeguarding of maternity by affording medical students for the first time the opportunity of gaining practical obstetrical experience in the course of their training. But Budin is chiefly important because by inaugurating a modern system of scientific care of infants he was instrumental in lowering the high infant mortality rate in France. Distressed by the ignorance of the mothers in caring for their babies after birth, Budin opened in 1892 his first "Consultation des Nourrissons" at the Charité hospital in Paris and began his campaign against the great waste of infant life caused by gastroenteritis. Babies were brought each week for weighing and examination, and for those who could not be breast fed the clinic distributed sterilized milk sealed in bottles containing the proper amount for each feeding. The results were so gratifying that similar centers were

established elsewhere in Paris and, after the formation of the League against Infant Mortality in 1902, were extended to all parts of France. In his book, *Le nourrisson* (Paris 1900), Budin made available the knowledge gained from his experiences in the infant welfare centers. His work has proved a great incentive to the present systems of child welfare.

BUFFER STATE. This term is often used to describe a weak state, small in size, probably without a positive foreign policy of its own, which lies between two or more powerful states and thus serves to inhibit international aggression. Such a state may be a result of historical accident, as in most historic cases. Or it may conceivably be the deliberate creation of the neighboring larger states or of a wider international concert; it seems impossible, however, to indicate any definite example of such a procedure, and perhaps it is more accurate to say that a buffer state is recognized and maintained as such by international agreement after it has come into existence by natural growth. With the development of powerful national states, especially in Europe, this practise has to some extent gained favor, although it cannot be said to have attained any general or well recognized status as a device in international relations. The policy which it represents has thus far been followed chiefly in connection with the maintenance of the balance of power.

In order to insure the continued existence of the buffer state its independence may be guaranteed by agreement among the neighboring states. Such an arrangement may be carried further and the territory of the buffer state may be formally "neutralized," i.e. rendered immune to invasion and utilization as a theater of war. If, however, the neighboring states wish to reinforce such an agreement by any restrictions upon the power of the buffer state to formulate and follow a foreign policy of its own, to maintain armaments, to engage in military action or to carry on any other independent activity, its consent must first be obtained. It may be worth while for the buffer state to accept the restrictions in consideration of the presumably greater security which it is to obtain by the guaranty. In any event the buffer state is compelled by circumstances to maintain relatively non-aggressive and neutral relations with its

neighbors, since its position is difficult and dangerous at best.

Belgium presents the clearest and most familiar example of a buffer state; another example is the Netherlands, although it stands less directly in line between Germany and Great Britain than does Belgium between Germany and France. The position of Luxembourg is similar to that of Belgium, and Switzerland occupies a highly important buffer position among her neighbors, Italy, France and Austria. The Baltic states and especially Poland, as well as Rumania and the Balkan states, have in the past, and do still to some extent, served as buffers between Russia or Turkey and central European powers. Great Britain has to some extent utilized Persia and Afghanistan as buffers between Russia and India; another example in Asia is, perhaps, Manchuria which, however, is not an independent state. In South America Uruguay and Ecuador may be regarded as buffer states although the absence of very aggressive foreign policies among the states of this continent makes their position less important.

The history of the past century does not augur well for the possible value of the buffer state as a deliberate device for the maintenance of international peace. It has proved impossible to create an independent Rhineland between Germany and France because both of these states have been unwilling to yield territory for this purpose. Moreover the buffer state is not easily persuaded to surrender its rights under circumstances which normally allow active foreign policies to be maintained and to rely upon an international guaranty or neutralization which may prove ineffective in time of need. It is likely to prefer alliance with one of its powerful neighbors and thus to disturb the balance of power. Where the buffer state exists naturally it may serve a useful purpose, but even here the situation is delicate and difficult for all concerned. In the past the force of national foreign policy and military aggression has been too strong, and international protection too weak, to render secure or stable the situation of even the guaranteed buffer state. Neutralization of restricted areas, portions of buffer states or frontier zones, may prove to be more satisfactory, but the elimination of international aggression would seem to be the only effective remedy for threatened attack by one state upon another.

BUFFON, GEORGES LOUIS LECLERC, COMTE DE (1707-88), French naturalist. With his appointment in 1739 as intendant of the Jardin du Roi at Paris Buffon's studies, which had hitherto remained diversified, received direction and purpose; ten years later he began the publication of the *Histoire naturelle* (44 vols., Paris 1749-1804; in *Oeuvres complètes*, ed. by Pierre Flourens, 12 vols., Paris 1853-55), with which he was to be occupied throughout the remainder of his life. Buffon approached his task with the objectivity of a pure scientist, aiming to collect and synthesize the scattered facts of natural science known to his day. This objectivity was in part responsible for his position of high authority among his contemporaries, who carried over many of his ideas to the sphere of social thought. To Buffon man was no more than a link in the animal series; while life in society favored the exceptional development of man's intellectual and moral faculties, these had their origins in sensations and instincts not radically different from those of other animals. He affirmed the unity underlying the diversity of human races, maintaining that all variations could be explained as the effect of purely physical and external causes. Modern students have seen in these ideas, as well as in certain of Buffon's observations on animals in general, indications that he glimpsed the notion of biological evolution. His theory of man was restated by the *encyclopédistes* and integrated with the psychological theories of Condillac; thus Buffon considerably affected the early development of anthropology. Another important influence on eighteenth century thought issued from Buffon's geological theories, set forth in his *Époques de la nature* (published as vol. v of supplement to *Histoire naturelle*, 1779; separately published Paris 1892). The doctrine that geological time could be divided into epochs separated by great catastrophic disturbances was applied to human history. Supplementing and modifying the system developed by Bossuet in his *Discours sur l'histoire universelle*, it furnished the basis for eighteenth century philosophies of history—notably Voltaire's *Essai sur les mœurs*.

BUGEAUD DE LA PICONNERIE, THOMAS ROBERT, DUC D'ISLY, (1784-1849), French soldier, politician and colonial administrator. Bugeaud was one of Napoleon's Imperial Guard, with a long military record. He was retired to his Périgord domain after the second restoration of the Bourbons and acquired a reputation as a scientific agriculturist. The July Monarchy brought him into politics, and as a deputy his voice was often heard on behalf of military, protectionist and agricultural interests. His greatest work was in the pacification of Algeria, which was begun in 1836. Within four years he had driven the Arab raiders up to the fringe of the Sahara. His contribution to colonial policy was his conversion of his soldiers into colonists. Colonization "by sword and plow" was his aim, and his rule as governor general (1841-47) was the most fecund period of Algerian colonization both in the number and variety of his experiments; his policy of cooperating with the Arabs was half a century in advance of his era. But as time went on he emphasized the military element of his plan more and more, because the lack of discipline among time-expired men and private settlers provided no safeguard against the Arab forays. Droughts combined with the opposition of the civilians to weaken his plan, and finally the French government, always lukewarm about his schemes, refused the necessary credits, and he resigned. Despite the anticlimax he had broken the power of the Arab emir, Abd-el-Kader, had colonized a new province for France, had revived the faith in Algeria shattered by the native revolts and had bequeathed a theory of military colonization to his fellow countrymen and to the British. "Père Bugeaud," as he was known, became a legend in French Africa, and although his reputation with his contemporaries was rather mixed his influence remained. His writings cover colonial, military and economic topics.

BUGENHAGEN, JOHANNES, (Pomeranus) (1485-1558), German educator and leader in the Protestant Reformation. Bugenhagen was born in Pomerania and studied at Greifswald. After a successful career as rector of a Latin school at Treptow he joined Luther in Wittenberg in 1521 and became professor of theology and pastor. In 1528 began the period of his constructive activity for the sound establishment of Protestantism in northern Germany. His fundamental contention was that the success of the Reformation depended on the intelligent and educated support of the people. In a series of ordinances (Brunswick 1528, Hamburg 1529, Lübeck 1531, Pomerania 1535, Denmark and Norway 1537, Schleswig-Holstein and Hildesheim 1542 and Brunswick-Wolfenbüttel 1543), in which he laid down the principles for the organization of the church, he therefore assigned an important place to education. He consistently urged as the duty of parents and of civil and ecclesiastical authorities the maintenance of elementary and Latin schools as well as schools for girls and, in the later ordinances, rural schools. He advocated a definitely articulated system of education and a radical improvement in the status of all teachers, recommending not only adequate salaries but support in sickness and old age. His vision did not stop with schools for the young; in several ordinances he suggested the organization of *Lektoria*, in part as preparation for the universities, in part for adult education in theology, philosophy, law and medicine. For the masses periodical expositions of the Bible and catechism were to be given in the churches.

BUILDING AND LOAN ASSOCIATIONS and their English counterpart, building societies, are cooperative or quasi-cooperative institutions engaged in financing through mortgage loans the building and purchase of houses. The use of the word "building" is probably accurate

for the very early societies but misleading when applied to most of these organizations at present. Although the modern associations developed from one original type found in eighteenth century England they exhibit a multiplicity of differences in methods of organization and operation. In a sense the existing differences represent merely various stages of development, which proceeded as a gradual organic adaptation to changing conditions. It is characteristic of these societies that throughout their history they were not influenced by deliberately constructed programs based on social or economic theories and that they have taken root in English speaking countries only. On the continent analogous needs of moderate or small income families have been met by land mortgage banks, general cooperative credit organizations, cooperative housing and building associations which often retained ownership of the buildings, and by various forms of government aid to housing.

Building associations and societies are defined at one extreme as mutual cooperative financial institutions and at the other as private corporations for profit. Mutuality was one of the original basic principles of these organizations. Its persistence to the present time is due only in part to its high repute; favorable legislation, particularly exemption from certain types of taxation, has been an important contributing cause. The decline in mutuality is evidenced not so much by the number of associations remaining faithful to it as by the decreasing rigor of its application. During the early stages the relations between the associations and their members were strict and exclusive. The transactions of the associations were confined to members, and shareholding was the only way of participating in the benefits the association might afford. On the other hand members were tied to the association by heavy engagements. Membership implied not only regular payments for a considerable length of time but also the risk of losses, which could make these obligations practically indefinite. Moreover, a member could not cancel his membership and withdraw his shares before maturity without incurring heavy penalties. His interests were thus sacrificed to those of the association, and the more mutual an association the more the association overshadowed the individual. It is in the manner of treating members that the process of modernization is best revealed. It is as easy to become a member of a large modern building association as to with-

draw; members' obligations are minimized and are becoming strictly defined. At present the association, far from being served by its members, undertakes obligations toward them. Thus the difference between a mutual and a non-mutual association is disappearing. Both deal with "customers"; both offer a certain service. There is a trend in modern associations to reduce membership to a mere formality corresponding with the tendency for dividends more and more to resemble fixed interest rates. The "membership share," for a long time the keystone of building association business, while still retaining its old form performs more of the functions of the deposit. In spite of the various legal definitions and provisions still in force "investing members" are in increasing numbers becoming depositors or investors; and since loans in many associations are no longer repaid by maturing shares, "borrowing members" have ceased to be interested in the affairs of the association and are coming to resemble ordinary borrowers. Thus as a result of growth old specific practises and principles of "building and loan" are disappearing and these organizations are following other financial institutions and adopting up to date business methods.

Another instance of the modification of early building association principles is found in the transition from the terminating to the permanent plans. All the early associations and societies were of the terminating type and within this form of organization many of the specific practises of the present associations were forged. In the old terminating association, often styled "building club," the members subscribe to shares of stock of the association ("instalment" or "membership shares") and make regular contributions (dues) on each share until it reaches its "matured" or par value (frequently \$200 each). Then the association is "terminated" and the assets divided among the members. The first American association, the Oxford Provident Building Association of Philadelphia County founded in Pennsylvania in 1831, was of this type. "In this primitive association there was only a single series of stock issued. . . . At the regular monthly meetings of the shareholders, held in the evening, the dues were paid in . . . and the funds received were offered in open meeting and the right to a loan sold to the highest bidder. . . . In the event no one wanted to borrow, parties holding shares upon which no loans had been made were compelled to become borrowers. These were called 'forced

loans'" (quoted from an address by Seymour Dexter in Clark and Chase, p. 459-60). The terminating plan is not in common use in the United States at present. It is still used by some three hundred small societies in England and is also found in the British dominions, especially in New South Wales where it is still the most popular type. The only country in which terminating societies are forbidden seems to be Canada, where they were prohibited by law in 1900.

The first permanent type introduced was the serial plan, which until recently was that most commonly used in the United States; it is still in general use in Pennsylvania, New Jersey, Illinois and Massachusetts. The serial plan repeats the main features of the terminating plan, but instead of using a single group of shares the serial association offers new groups or "series" of shares for sale at periodic intervals, annually, semi-annually, quarterly, monthly. "It is in a sense an association of an indefinite number of associations of the terminating type, each series in turn going through the processes of starting, functioning to maturity and then disappearing as its loans are liquidated and its 'free shares' retired" (Clark and Chase, p. 39). The serial plan is found only in the United States.

Other varieties of the permanent plan which developed from the serial type are the regular permanent and the Dayton permanent plans. Associations using the regular permanent plan issue shares not in series at stated periods but at any time. Each shareholder has an independent account and his shares start and are matured without being grouped with others. The regular permanent plan seems to be a transition from the serial to the Dayton permanent, which is more correctly styled the optional payment, plan ("deposit shares"). Under this plan payments are not restricted to the regular dues; each member may pay in any amount at any time or may suspend making payments. This plan is becoming the most common and is used by all the larger institutions in the United States and in England. Thus is indicated the gradual disappearance of the principle of compulsory regularity in the payment of dues on instalment shares. This principle applied for generations made the building associations a stern school of thrift. However, its application was accompanied by many abuses in connection with penalties (fines, forfeitures, withdrawal and membership fees) used to enforce regularity. The abuses are now being gradually eliminated and at the

same time the principle is falling into abeyance.

In addition to the instalment shares many associations in the United States issue fully paid up stock, thus departing still further from the original terminating-mutual type of building association. The outstanding type of this issue is the "guaranty stock" permitted by some state laws. It derives its name from the fact that the capital obtained through its issue is used to guarantee dividends on other shares and other liabilities of the association. Earnings in excess of liabilities accrue to the benefit of the guaranty shareholders and the latter exercise control over the association's affairs. Thus the functions of the guaranty stock are identical with those of the capital in a bank. This plan is used by an increasing number of associations in California, Kansas, Oregon, Texas, Utah and, with some modification, in several other states. The guaranty and the serial plans may be considered particularly characteristic of the American development, the former representing in a sense the last stage of modernization and the latter being the most orthodox of the specific "building and loan" methods.

The "local principle," which is a specific feature of American development, is also being gradually abandoned, although not as rapidly and radically as the others. The early institutions were all local just as they were terminating—not on principle, but because it was natural for an organization to be formed by people who had specific needs and who were bound by neighborhood ties. The limitation of membership to a restricted locality became a "principle" after the failure of the "national" building associations in the nineties. So great was the reaction in public opinion caused by the "national fiasco" that in spite of the disappearance of the old national associations there is still a hostility against this type of organization. In most of the states associations incorporated in another state ("foreign") are restricted, and in some states they are still prohibited. Most associations restrict their mortgage operations to one state, county or other limited territory. For instance, one of the largest associations in the United States and a perfect example of a modern mutual building association, the Railroad Co-operative Building and Loan Association of New York, with assets exceeding fifty-five million dollars, confines its mortgage service to a fifty-mile radius. The law of New York state formerly placed this limitation upon the associations, but a recent change permits loans to be made within one hundred

miles of the association's home office. During recent years the process of centralization and concentration has been gaining ground. Many associations, especially of the guaranty type, have established branches in their own and in other states. There is also a tendency toward amalgamation among some of the numerous small associations and among some of the guaranty type associations, especially in California, a tendency toward consolidation of control through holding companies. Moreover, there are developing new methods of cooperation between associations, which do not interfere with the local principle. The Land Bank of the State of New York, established in 1914 as a semi-public institution, is an interesting experiment in this direction. Associations in various states are creating special reserve systems for their own use. In California the Building-Loan Federation was established in 1928. In Ohio, through the Ohio Building Association League, associations have created a fund of two million dollars placed with New York banks, which makes available for emergency a credit of ten million dollars. In Florida there has been organized a Building and Loan Reserve Association for a similar purpose. An important project designed to bring about coordination among the associations throughout the country on lines similar to the Federal Reserve system is under discussion.

In England, with its strong, highly centralized individual societies, nothing has as yet been done to create special reserve systems. There is less need for them since, in the absence of legal limitations as to territory served, the larger societies operate all over the country. The largest English society, the Halifax Building Society, which was created by a recent amalgamation, has assets of about \$300,000,000, representing something like one fifth of the total assets of all societies in England. This society has more than 350 branches and is far larger than any single American association. The tendency toward centralization combined with a large number of dissolutions of terminating societies is responsible for the rapid decrease in the number of English societies, whereas in the United States the number of associations is increasing from year to year.

Building and loan associations function as savings institutions and as home financing agencies; in both fields they have attained and preserved a distinct place. In the savings field they developed in competition with savings

banks specialized methods of attracting funds and secured a special clientele. However, with the increasing tendency of building associations to sell their instalment shares upon virtually the same terms as ordinary deposits and with the spreading of the guaranty plan in some parts of the United States, the difference between building associations and savings banks is diminishing. Their chief attraction for investments, as compared with savings banks, is the higher rate of profits which they pay. But this difference too is becoming less marked, since the tendency among the associations is to lower the rate of interest charged to borrowers with a corresponding decline in the rate of earnings.

In the lending field, building associations specialize in mortgage loans on the instalment plan for the acquisition and building of houses, especially small residences. Perhaps one of the most important reasons for the absence of these associations on the continent is the prevalence there of housing in tenements as contrasted with the English and American preference for small, single family houses. For many years building associations were virtually the sole agencies for first mortgage loans on small residences and are still representative of what is called by R. T. Ely "the American method of acquiring a home." They succeeded in making this class of mortgages a sound investment and are meeting with increased competition on the part of insurance companies and other financial institutions controlling large funds. As a result there is a growing recognition of the necessity of extending to borrowers better service and easier terms.

In England and in most of the states of the United States no legal limitations are imposed as to the kind of real estate that may be accepted as security for a loan, but most associations lend only on dwelling houses and give preference to owner-occupiers. The loans are usually repayable by uniform monthly or weekly instalments of principal and interest spread over a period of years (usually from five to fifteen years). This system permits the lending of a larger proportion of the property value as the amount advanced is reduced with every periodical payment. The margin between the value of the property and the amount of the loan required by American associations varies greatly. In some states loan limitations are imposed by law. In England the amount of the loan is usually limited to three fourths of the value of the property; however, local authorities are empowered by the Housing Act of 1923 to give

guaranties enabling building societies to lend under certain conditions up to ninety percent of the valuation of houses. Some insurance companies issue guaranties for the same purpose (mortgage guaranty scheme). In recent years the combination of life insurance with the amortization of mortgage loans is becoming popular in both England and America.

The social significance of building and loan associations, as well as their position among other financial institutions, rests upon the peculiar way in which they combine saving and lending features. They have succeeded in stimulating new sources of thrift and in making additional funds available for housing. Their usefulness was best tested during the period of extraordinary housing shortage following the World War. The rate of growth of building associations in this period exceeded that of other financial institutions and was quite different from their own previous experience. The development in the United States is presented in the table below:

YEAR	NUMBER OF LOCAL ASSOCIATIONS	MEMBERSHIP (IN MILLIONS)	ASSETS (IN \$1,000,000)
1893	5,598	1	473
1913	6,429	3	1,248
1918	7,484	4	1,898
1923	10,744	7	3,943
1928	12,666	12	8,016

In England, too, building societies started their golden age after the war. Within the last ten years they have increased their assets about three times and have more than doubled their membership. In 1929 there were in England about one thousand societies with a membership of about a million and a half; they held assets amounting approximately to £300,000,000. It is estimated that about 1,800,000 families in the United States and about 500,000 in England are financing their homes through building associations and societies. The existence in England of municipal housing and the granting of municipal mortgages to owner-occupiers, and the absence of both in the United States, are factors to be considered in comparing these figures.

The distribution of building associations, their success and growth, vary considerably from state to state and from locality to locality within the state territory. Pennsylvania with 4272 associations and \$1,340,000,000 assets headed the list for the year 1928 as for previous years. Ohio was second with more than one

billion assets. Next came New Jersey, Massachusetts, Illinois, New York, Indiana and California. These states combined have far more assets than the associations in all the other states. The highest rate of growth in assets during recent years was shown in the newer sections of the country. During 1927 Texas showed an increase in assets of 30.8 percent and California of 27.2 percent. In England building societies are especially strong in Yorkshire, where the few largest societies are located. The highest rate of growth during recent years is shown in the London area.

In the early stages building associations and societies were not incorporated and were not subject to legislation. The first American act relating to building associations was passed in Pennsylvania in 1850. At present most of the states have special laws providing for the organization and supervision of building associations. The existing legal provisions vary from state to state and contribute to the lack of uniformity in the practices of building associations. Moreover, these laws are subject to frequent revision. The main object of these enactments is to combat the attempt of speculative promoters to exploit building associations for their own benefit; they are also designed to eliminate such abuses as the imposition of exorbitant fees, fines and forfeitures. Supervision is exercised by state officers through the examination of the books of the associations and of their periodical reports. In England building societies are under the Building Societies Act 1874-94, and the supervision is exercised by the Registrar of Friendly Societies.

The building associations and societies are organized into a number of leagues and institutes for the protection of their interests and for the maintenance of standards of service. In the United States there exist several state leagues and the United States Building and Loan League, formed in 1892. The corresponding body in England is the National Association of Building Societies founded in 1869. In 1922 the American Savings, Building and Loan Institute was established for educational and research purposes. The leading organs are the *American Building Association News*, published monthly since 1880 in Cincinnati, and the *Building Societies' Gazette*, established in 1869 in London.

Outside of the English speaking countries "building and loan" methods are little known. An attempt to introduce them was made in Germany by the establishment of *Bauspar-*

kassen. The first institution of this kind, *Bausparkasse der Gemeinschaft der Freunde*, started business in a little village, Wustenrot, in 1924. In 1929 it had mortgage assets of about \$20,000,000 representing savings of people anxious to build their homes. The success of this example induced many others in Germany and also in Austria to follow. At present the continental type of building associations is still in the making. So far the main difference between the *Bausparkasse* and the English or American association lies in the absence of voluntary investors in the former: *Bausparkassen* accumulate all their funds from prospective borrowers. A feature of the most recent development was that some German savings banks controlled by public authorities were induced by the success of the private associations to establish similar institutions of their own. Owing to the exceptional housing stringency felt in many countries and to the difficulties experienced by the existing agencies in coping with the financial aspect of the problem, it is possible that building associations' methods may become better known and more widely used.

BUILDING REGULATIONS comprise laws, ordinances and rulings designed to guard the safety, health and welfare of persons in and about buildings. As constituted today they represent the results of experience through many years and in many countries.

From the sticks and stones of the savage to the towering heights of the modern skyscraper is an evolution in construction in the course of which men have been forced to sacrifice a certain amount of private independence in the interest of public safety. Buildings of primitive times, representing as they did an individualistic working out of the application of available materials to the purpose in hand, namely, protection from the elements, presented few construction problems. This was particularly true of nomadic tribes. With more settled conditions, however, there came inevitably the need for preventing injury to one's neighbors caused by selfishness, ignorance or incompetence.

Building regulations are by no means a modern phenomenon. They reach back into the roots of civilized history wherever people have settled down in towns and cities. The Civil Code of Hammurabi, which dates back to about 2100 B.C., has a passage as follows: "If a builder build a house for a man and do not make the construction firm, and the house which he has built collapse and cause the death of the owner of the house, that builder shall be put to death." Therein lies the principle which has become fixed in our building regulations today—that they exist to prevent injury and not, as some well meaning persons would have it, to confer a benefit.

In China building regulations can be traced back to at least a thousand years before the Christian era and these ancient regulations are said to be influential in preserving much of the construction in that country as it was three thousand years ago. Height, depth and breadth of buildings, the number of courts and similar details were all covered.

Thickness of party walls and other municipal regulations are to be found in the laws of the

Roman emperors. Particularly did these rulers appreciate what sanitation means to a great city. The stringency and thoroughness with which laws regarding private sewers were covered are apparent from the *Corpus juris civilis* of Justinian. These excellent sanitary regulations and some of the other regulations disappeared in the chaos of the Middle Ages, to reappear in later times after some terrible lessons had been taught by pestilence.

Rather detailed regulations as to party walls, gutters and sanitary precautions appear in Fitz-Elwyn's Assize, which is the pioneer English building act. This was ordained in 1189 in the reign of King Richard I. It provided legal means for ensuring fairness and proper enforcement. London, seared by the great conflagration of 1666, took steps in its building regulations to make such events less likely in the future. Present day London regulations date from the laws of 1894; since then some modifications have been made to cover modern conditions.

Sometimes regulations have proved to be in advance of their time, as was the case with that promulgated by George Washington in 1791 to the effect that the outer and party walls of all houses within the city of Washington should be of brick or stone. The hampering effect of this regulation upon those of moderate means caused its suspension soon afterwards.

Early building regulations in the United States dealt with rather simple questions and in simple terms. The delineation of fire limits, thickness of walls and similar matters comprised all that was deemed necessary. Construction was relatively simple in type, the weight of buildings and of their contents being transmitted by girders or beams to solid masonry walls and thence to the foundations. Walls were required to be progressively thicker toward the lowest story in order to carry the accumulated weight of the structure above. Requirements were generally phrased in terms of thickness rather than in allowable stresses. Such construction reached the natural limit in height at from six to ten stories, partly because of the fact that the increasing thickness of walls left insufficient room on the lower floors and partly because tenants refused to walk up beyond a certain distance. In the latter part of the last century the coming of the elevator and of the skyscraper type of construction, in which loads were carried on a steel framework and the walls merely served to shut out weather, caused a revolution in construction methods. Naturally old time

Building and Loan Associations — Building Regulations 53

regulations failed to cover such innovations and had to be modified to keep in step with progress.

The skyscraper is generally credited with arriving in the eighties, but did not push its way to extreme heights for some time thereafter. Its construction was predicated on engineering principles demanding rather intricate mathematics, and the regulations concerning it bore strange contrast to the simple requirements for its wall bearing predecessors. Not long thereafter a new type of construction based upon a combination of concrete with steel reinforcement began to forge ahead and came into full prominence in the beginning of the present century. Here again engineering formulae had to be developed and applied in controlling a type of construction for which there was no precedent. Building regulations have thus tended toward greater complication as the inevitable result of new inventions. As a further illustration of the effect of modern inventions there may be cited the application of electricity to lighting and other functions in buildings. This is a development mostly of the last half century, and dealing with it meant the evolving of regulations for something which did not exist, except on an experimental scale, within the memory of men now living.

Originally there grew up a trilogy of basic reasons for controlling construction: protection against fire, to prevent the public calamity of conflagration and to conserve life; insurance of structural strength, to prevent collapse with consequent personal injury; and guarding of incoming water and outgoing wastes from buildings, to prevent spread of disease. It will be noticed that all this is done to prevent injuries, and little thought is required to see the instant application. Extensions have come with modern inventions. Electricity has to be guarded and controlled in its course through buildings; boilers and elevators have to be inspected. Beyond these rather obvious extensions, however, have come some which have fought their way through to general acceptance because of their demonstrated application to human health and welfare. Of such is zoning. The coming of high buildings has increased the problems of proper light and ventilation—subjects which are just beginning to be covered adequately. Fortunately science has stepped in at the right moment to demonstrate the health giving qualities of sunlight and has furnished something more than a sentimental or purely legalistic reason for preventing one man from appropriating more than

his fair share of what rightfully belongs to all.

Other currents are flowing toward the general stream, perhaps fated to disappear before merging with it, perhaps destined to eat their way through legal obstacles. Control of the aesthetic features of buildings takes its place in these. A few attempts have been tried at it; others are in contemplation. It is true, however, that many regulations of primarily utilitarian purpose, principally the zoning ordinances, have had the indirect effect of considerably influencing the appearance of buildings.

Back of all building regulations, giving them force and vitality, stands the police power. It is a power inherent in the states and usually delegated to some extent to the municipalities when their charters are granted. Some state governments exercise this power freely, passing laws which go into considerable detail. Others adopt a more flexible method such as providing for an administrative board which is empowered to draw up and enforce regulations. Still others are content with only meager legislation on the subject, leaving the towns and cities to adopt ordinances as they think best. Sometimes the county is the unit which prepares and enforces the building code. Wherever state legislation exists it takes precedence over local enactments, which may be more detailed and restrictive but may not negative anything in the state law. Enforcement is usually a local affair, although state factory, tenement, school house and hotel inspectors are not uncommon, and state officials occasionally work side by side with local authorities.

As they stand today regulations on fire limits and fire protection, strength of materials and structural members, and assumed loads in design constitute the bulk of building codes. Sometimes found in the same documents but frequently enforced by other departments than the building department are the plumbing and electric codes and regulations concerning the inspection and maintenance of elevators, boilers and other building equipment. Regulations concerning where particular types of occupancies may be located, maximum heights of buildings and percentage of lot area that may be covered by buildings appear in the zoning ordinances. Overlapping building and zoning ordinances in some of their provisions are state and local housing acts which are concerned chiefly with provision for proper lighting, ventilation and sanitary facilities. Sometimes their provisions apply only to public and semi-public buildings.

There are also the host of acts bearing in some way upon building construction in which working or living conditions in factories, tenements, schools, hotels and similar structures are guarded. It is thus apparent that there is a broad range of interest and diverse methods of application contained in contemporary building regulations.

In the United States there is wide divergency in requirements upon a given topic in the building codes of different localities. With no central organization to formulate requirements each political subdivision has adopted what is desired, using such information as was available at the particular moment. In other countries, where centralization of government sweeps away the complexities arising from the delicate relations of nation and state, country-wide codes are possible and common. Japan, for instance, has such a code for building construction.

While uniformity in building requirements is highly desirable from the standpoint of both safety and economy it does not necessarily follow that all requirements can be stated in the same terms throughout the country. Minor variations must of necessity persist because of peculiar local conditions. For instance, experience with earthquakes in certain sections will dictate certain precautions which would not be justifiable where such phenomena are of rare occurrence. Similarly the prevalence of tornadoes and hurricanes determines unusual measures in some localities. Regulations have suffered, however, from the tendency to produce requirements by copying those of other cities, which may not have been correct in the first place. Some curious regulations are still found today in certain codes which have apparently survived in this manner long after the regulations in the original code from which they were copied have been corrected. Uniformity is in the main both desirable and possible. In stress requirements, for instance, there is no apparent reason why the same grade of steel should not be permitted the same stress under given conditions without regard to locality. Equally possible is the use of uniform minimum live load assumptions.

Perhaps the most important application of uniformity from the standpoint of the architect and contractor doing business on a nation-wide scale is the manner of presenting code requirements. A uniform method of doing this would save many hours of groping for complete information and would tend to better observance

of regulations because of better familiarity with them. When requirements are selected with no regard for consistency and with no resemblance to methods of presentation in other codes, even the builder seriously desirous of observing the law may run afoul of it because he has missed some point. As matters stand now, long hours of conversation with building officials must be held to determine points which could readily be looked up and observed if they were properly presented in the code. Present day tendencies in building codes, however, are undeniably toward a greater degree of uniformity in requirements. Lethargy of legislative bodies will continue to be responsible for obsolete and obsolescent requirements in some instances, but public insistence on common sense methods of protecting public safety will sooner or later prevail.

The time may soon be expected when there will be little dispute about the facts to be used. There appear to be developing two opposite methods with regard to the statement of requirements. One which is prominent for the moment depends upon a rather detailed treatment with explicit directions amounting almost to a specification. Its merit is that there is little room left for argument between a building official and a recalcitrant builder. Its inherent weakness appears to be too great rigidity in presenting requirements, and holding down the competent and skilled designer to the level of the mediocre man in order that there may be no possibility of failure.

The other method of treatment is general in tone. It lays down results rather than methods, states what performance should be expected of each structural part or what general principle should be observed and leaves it to the skill of the designer and builder and the vigilance of the inspector to see that results are obtained. Its great virtue is in giving the public the advantage of new processes, new materials and new developments in scientific thought, stimulating rather than inhibiting progress. It does not drag down the good architect and engineer to the dead level of the mediocre man in the profession. New materials are automatically admitted to use on satisfactory proof to the building official that they are capable of performing the function for which they are intended. A possible defect of this type of regulation is that in stating results rather than methods it places too much trust in the enforcement officials. The truth is that no code, however carefully drawn and however complete, can hope to cover every possible con-

tingency, but must leave many points to the discretion of building officials. It is better to maintain a well paid and intelligently manned building department with broad discretionary powers than to deprive the public of the best design that it is possible to obtain.

The hampering influence upon architectural and engineering design of inflexible code provisions is illustrated by stress requirements. In some communities they are obviously based upon crude conceptions of earlier years when accumulations of testing data were not available and a factor of safety of large but unknown amount was used. Today it is possible to design with greater assurance in the light of rich stores of basic information. Yet the skilled designer is frequently prevented from taking advantage of this situation. While revolutionary developments in construction do not occur frequently new materials and processes are being developed daily. Welding of steel members in place of the ear splitting riveting now customary may serve as an example. It should be the function of good building regulations to recognize such developments when they prove themselves, without the necessity of obtaining sanction from purely legislative bodies. In times past, efforts to introduce worthy new materials have met with open or covert opposition because the promoters of older materials with strong vested interests feared the new competition and had sufficient political influence to exclude the newcomer. The public was thus deprived of the economy to be derived from new processes.

It would be profitable for a community to scrutinize its building code provisions at regular intervals—probably five years is not too short a period—to see that everything is as it should be. Especially is this true in times of mounting costs of construction when more efficient ways of utilizing materials may be sanctioned which will encourage construction that would not otherwise be undertaken. Obsolete and unscientific requirements are responsible for a greater amount of hindrance to city growth than is commonly suspected. Anything that tends to keep construction costs up or to discourage the full application of skilled architectural and engineering talent tends to divert construction to more receptive territory and creates a differential in building costs between such communities and more progressive ones. The other side of the picture of course is of even greater importance, for neglect of precautions against conflagrations and epidemics may have disastrous consequences.

The local enforcement of building regulations is entrusted to an official variously termed by such titles as "Superintendent of Buildings," "Building Commissioner," "Building Inspector." Enforcement of zoning regulations as well as those contained in the building code usually rests with this official. Customs differ with respect to regulations regarding boilers and electric wiring. In some cities these form subordinate branches of the building department while in others they are independently administered. A favored administrative procedure with regard to plumbing is to place enforcement either directly in the Board of Health or in an official responsible to that body. In some localities electric inspection is done by representatives of insurance interests, a measure of rather dubious legality.

Enforcement is sometimes paid for by a sliding scale of permit fees, occasionally supplemented by fees for inspections. As a general rule permit fees do not pay entirely for the expenses of the department. In some instances, however, they bring in much more revenue than is used for inspection purposes and this has occasioned considerable question as to the wisdom of using the building department to swell the general funds of the city. The argument is presented that building owners must pay taxes on their property and that any charges beyond those necessary to pay for inspection are unjustified. Many municipalities make no charge of any sort, the expenses of the administration being paid for out of the general funds of the city. Still a third method of handling the matter is to require the owner of a building to employ a resident inspector whose salary is provided by the owner. This inspector is required to furnish to the building department satisfactory evidence of his qualifications and to make frequent reports on the progress of the work. The building department is supposed to check the quality of his inspection and can revoke his authority to conduct inspection if it finds him incompetent. Usually this type of inspection is confined to buildings of considerable size or to special types of construction.

As might be expected the quality of building inspection is extremely variable. In a good many small communities it is of a very informal sort and the rigidity of inspection is determined very largely by the character or qualifications of the person willing to accept a generally unremunerative job. Local politics and pressure of influential material industries are often factors in determining the grade of enforcement. Many

larger communities, however, have well organized departments manned by able administrators, although salaries of inspectors are not always of such size as to command the continued services of well qualified individuals. Large cities have elaborate organizations, often with differentiation in duties. One man, for instance, will specialize in checking plans, another in inspecting reinforced concrete and a third in determining the condition of elevator apparatus. Thoughtful building inspectors have made tentative attempts at defining a measure of quality of building inspection, but this study is in its infancy. Such conditions as geographic area to be covered, topography, prevailing types of construction and effect of political pressure have to be considered in arriving at even a tentative conclusion. It is not improbable that a standard can be arrived at whose worth can be determined experimentally. The finding of some method of gauging the manner in which the safety of construction can be assured is of obvious importance to the public.

A significant development is the rise of organizations of professional and scientific men or of manufacturers of building materials. These have worked earnestly toward producing sound standards for utilizing the various materials that enter into construction. The roster is a long one. Mention of such organizations as the American Society of Civil Engineers, the American Society for Testing Materials, the American Society of Heating and Ventilating Engineers, the American Concrete Institute, the American Institute of Steel Construction, the National Lumber Manufacturers Association and the National Fire Protection Association merely touches upon this aspect of the subject. Testing of materials has assumed an ever growing importance and the accumulation of data has furnished a basis on which many structural requirements may be determined. As before, mention can be made of only a few of the places where such tests have been made, but those conducted at the Watertown Arsenal, Columbia University, the Underwriter's Laboratories and the Bureau of Standards at Washington are of special importance. The amount of work fundamental to building regulations is steadily increasing at the last named institution because the public turns to it more and more for authoritative information. In a number of cases interested organizations have acted jointly to produce recommendations designed to be acceptable to all. Instances are the work of the Joint Committee on Standard

Specifications for Concrete and Reinforced Concrete and the preparation of the National Electrical Code.

Interest in all phases of building regulations has been quickened in recent years by private and governmental agencies which have studied the fundamentals of the subject and have prepared suggestions to serve as a guide to better requirements. The Department of Commerce through its committees on building codes and on city planning and zoning has provided a focal point for the assembling of fact and opinion and their interpretation by nationally known experts. The first of these committees has issued five reports dealing with various subjects commonly covered in building codes and a sub-committee has issued another report on plumbing. These reports, which contain recommended minimum requirements suitable for use in state and municipal building or plumbing codes, have found a wide field of usefulness. The work of the committee dealing with zoning and city planning has resulted in reports on "A Standard State Zoning Enabling Act" and "A Standard City Planning Enabling Act" which have been equally influential in shaping sound legislation.

The National Housing Association has concerned itself with the promotion of ideals of better housing. The Building Officials Conference and its western counterpart, the Pacific Coast Building Officials Conference, have labored diligently in the encouragement of sound building requirements. Zoning, scarcely heard of a dozen years ago, has leaped into prominence. Tenement legislation in New York has come in for rigid scrutiny by a committee of experts. All signs point toward a tightening rather than loosening of restrictions placed upon individual freedom in building. In the process, however, requirements are becoming fairer, more scientific and better adapted to the needs of our present civilization.

Today some eight hundred and fifty cities, towns and villages in the United States have zoning ordinances and about the same number have building codes. In well ordered communities these legal measures control virtually everything that rises above the ground and very much of the contents of such structures. Exploration of their somewhat forbidding terms offers an enlightening example of the regulation of selfishness, ignorance and incompetence in the interest of the community as a whole.

BUILDING TRADES. See CONSTRUCTION INDUSTRY.

BÜKHĀRĪ, MUHAMMAD IBN ISMĀ'ĪL AL- (810-70), Arabic scholar and collector of the Traditions of Mohammed. By Būkhārī's time it had become an established practise to refer all questions of conduct to the precepts and example of Mohammed and accordingly the sacred science of Tradition had developed. The materials with which it worked were the sayings of Mohammed, transmitted orally, and its problem was to sift out the authentic from the spurious and to restore them as nearly as memory and human accuracy would permit to their original form. The very title of Būkhārī's great work, *Al-jāmi 'al-Ṣaḥīḥ*, meaning the "authentic collector," attests his conscientiousness. At an early age he began his travels through the countries of Islam, visiting learned men in all the great cities and writing down the traditions he heard from them. His book is systematically divided into a great number of short chapters, each one preceded by a brief preface showing what practical conclusions are to be deduced from the traditions cited therein. He gives the texts literally as he heard them from his teachers and precedes each text with the full "chain" of traditionists who have related it, if

possible down to the Prophet. In some cases there are also short critical observations. The traditions deal with all problems of ritual, juridical, dogmatical and ethical matters discussed in the days of Būkhārī, and are still held as a pattern of authority in the Moslem world.

BUKŠEG, VILIM (1874-1924), Croatian labor leader. In his early travels as journeyman typographer Bukšeg came into contact with the labor movement in his own country and in other European states. After 1900 he became one of the leaders of the movement in Croatia, particularly in the spheres of syndicates and workers' insurance. He worked for the centralization of both these activities, serving first as secretary of the central office of the syndicates and in 1909 as chairman of the chief insurance treasury. Even the last years of his life were devoted to the extension of workers' insurance, particularly in his capacity as director in chief of the central office for workers' insurance in Jugoslavia.

Although throughout his career Bukšeg devoted himself principally to the economic and administrative aspects of the labor movement he was engaged in political activities as well. Especially after 1900 and during the Serb-Croatian struggle against the coercive regime of the Hungarian, Khuen Hedervary, he contributed often to the socialist press of Vienna, Berlin and Budapest. As head of the Croatian socialist party he worked for the rapprochement of Jugoslavian and Balkan socialists. He suffered imprisonment several times for his articles and manifestations in the cause of political freedom. After the World War he served as councilor for social welfare in the provincial government at his native Zagreb and as food minister in 1921. For several years after the war Bukšeg was president of the Workers' Federation of Jugoslavia.

DRAGOLJUB JOVANOVIĆ

BULGARUS. See FOUR DOCTORS.

BULL, PAPAL. Papal bull is a generic term commonly applied to letters emanating from the papal chancery. The word comes from the

leadon seal (*bull*) which was attached to the document by linen or silk threads. It carried on one side the representation of Saints Peter and Paul and on the other the name of the reigning pope. In course of time the term came to be applied to the document itself, although there is no official sanction for this. The term bull is not employed by the papal chancery. These letters are frequently designated according to their content as follows: constitutions, addressed to the whole church and pronouncing on matters of faith and discipline; encyclicals, letters of instruction addressed to all Catholic bishops or at times to bishops of certain states; decrees, rules of general utility for the church; decretals, decisions in a particular matter but of which the solution may serve as a general rule.

Not all papal letters are strictly bulls. From the middle of the fifteenth century many of the papal letters took the form of the brief, in which the leadon seal was replaced by one of wax, by which the folded ends of the parchment were fastened together. Ultimately this wax seal was superseded by a stamp in red ink bearing the same device, that of the fisherman's ring. The bull still continued for certain types of documents, e.g. for pronouncement of doctrinal decisions, sentences of canonization, promulgation of general indulgences and territorial reorganization of local ecclesiastical divisions. This discussion will include both bulls and briefs.

Bulls are written in Latin. Until the eleventh century the material employed was papyrus; since then parchment (sometimes paper for the briefs) has been employed. Until the pontificate of Leo XIII bulls retained much of their archaic form, being written in a special script (the *bullatica*) extremely difficult to decipher. Briefs have regularly been written in Roman script. The peculiar style of the bulls, their script and methods of authentication were adopted and for long retained in part at least as a precaution against the constant danger of corruption of the text or forgery, which were common throughout the Middle Ages especially prior to the thirteenth century. Innocent III (1198-1216) devised elaborate rules for the detection of forgeries and insisted that local prelates should be trained to judge the genuineness of the document. But this by no means ended the abuse. Even in recent times serious works have continued to carry the allegation that in 1456 Callistus (Calixtus) III promulgated a bull anathematizing Halley's Comet.

Papal bulls, of which there are unbroken registers covering the last seven hundred years, together with rich remains from preceding centuries, constitute a most valuable source for the history both of the papacy and of Europe. The earliest papal letters were of a semi-private character addressed chiefly to individual bishops throughout Christendom, offering advice, encouragement, admonition or censure and rendering decisions on points of doctrine or discipline. They were most often written in reply to definite queries on the part of members of the clergy. With the development of the papal monarchy, however, they early assumed a more public and oecumenical character and from the time of Hildebrand (Gregory VII, 1073-85) have become public documents of the greatest importance. They form the most considerable element in canon law and as such have had an important influence upon the development of legal theory more particularly in the Middle Ages. Through them the pope promulgates laws for all Christendom. Their significance was great, especially in the period prior to the emergence of the strong territorial state when the papacy played a decisive role in the political history of Europe. Reference to the registers of any of the popes of the thirteenth century will indicate the wide diversity of the problems dealt with in these documents. They reflect in a marked degree the political and social, as well as the religious and ecclesiastical, life of Europe.

Since the church is a universal institution, theoretically unlimited by arbitrary lines drawn to mark off one state from another, the pope has quite naturally assumed the right to communicate freely and directly with all Christians under whatsoever government they may live. In the Middle Ages the growing territorial state frequently saw in this an infringement of its sovereignty. By the fourteenth century, therefore, several European states had limited the promulgation of papal bulls within their boundaries. The case of England may not be entirely typical of such action, but will indicate its general character. As early as the eleventh century William I is said to have introduced the principle that all papal letters addressed to persons in England must be seen by him before their delivery. This policy was continued by William II and Henry I, but it later fell into disuse. As a war measure, in his struggle with Thomas à Becket, Henry II absolutely forbade the bringing in of papal missives. This action

was only temporary, but English kings regularly insisted that papal letters which might be considered prejudicial to the law or their prerogative be delivered to themselves. The Statute of Praemunire (1393), for example, made it a crime for anyone to purchase or otherwise to secure from the pope a bull or instrument that would in any way injure the king or the realm. As a result of the break with Rome, Elizabeth in 1571 issued an unconditional prohibition of papal bulls. The kings of France from the late thirteenth century restricted the free entrance of bulls into that country, and the same was true in Portugal. Similar action was taken more slowly in Germany. In every case these laws were directed against bulls of political import.

As examples of bulls certain famous papal letters of political or social significance may here be noted. In the struggle between Philip IV of France and Boniface VIII the latter promulgated three important bulls: *Clericis laicos* (1296) forbade the taxation of the clergy by the state without papal consent; *Ausculat filii* (1301) recalled Philip to his obedience to the pope and his duty to the church; and *Unam sanctam* (1302) embodied the highest claims to ecclesiastical and temporal supremacy ever advanced by any pope. In the struggle with heresy and schism the bull *Ad extirpanda* (1252), issued by Innocent IV, systematized the procedure of the Inquisitorial Courts in dealing with heretics; by the bull *Exsurge domine* (1520) Leo X condemned forty-one propositions of Luther and threatened the arch-heretic and certain of his friends with excommunication if they refused to recant; the bull *Unigenitus* (1713), promulgated by Clement XI under strong pressure from Louis XIV, condemned the Jansenists. An illustration of the position of the pope as an international arbiter is afforded in the series of three bulls promulgated by Alexander VI in May and September of 1493, establishing a "line of demarcation" in settlement of the rival claims of Spain and Portugal to recently discovered lands in the New World. But these bulls indicate also the weakness of the pope as international arbiter, since in the following year the two states concerned, independently of papal authority, established a new line by treaty.

More recent pronouncements of the papacy which have important social bearing are the encyclical *Quanta cura* (1864) and the accompanying so-called *Syllabus of Errors*, wherein Pius IX condemned the more liberal social, political and intellectual tendencies of the age,

and the encyclical *Pascendi* (1907) by which Pius X declared war on "modernism." The most widely influential and interesting pronouncement of the papacy in social matters, perhaps for all time, is the encyclical *Rerum novarum* promulgated by Leo XIII in 1891. In this the pope took a stand against socialism, while at the same time he suggested principles looking toward the amicable settlement of the conflict between labor and capital, declared that every working man should receive a living wage and upheld the right of laborers to combine.

Consult: Giry, A., *Manuel de diplomatique* (Paris 1894); Pflugk-Harttung, Julius von, *Die Bullen der Päpste bis zum Ende des zwölften Jahrhunderts* (Gotha 1901); Poole, R. L., *Lectures on the History of the Papal Chancery down to the time of Innocent III* (Cambridge, Eng. 1915); Tardif, Adolphe, *Histoire des sources du droit canonique* (Paris 1887); Richter, A. L., *Lehrbuch des katholischen und evangelischen Kirchenrechts* (8th ed. Leipzig 1884-86). The best known collection of bulls is the so-called *Magnum bullarium romanum*; the basis of this is the edition of Carolus Cocquelines (*Bullarium magnum seu novissima et accuratissima bibliotheca apostolorum constitutionum*, 28 vols. in folio, Rome 1739-62), which included bulls from the pontificate of Leo I (440) to the pontificate of Benedict XIV (1758). For a calendar of papal bulls to 1304, see Jaffe, Philipp, *Regesta pontificum romanorum ab condita ecclesia ad annum post Christum natum MCXCVIII*, 2 vols. (2nd ed. Leipzig 1885-88), continued by Potthast, August, *Regesta pontificum romanorum inde ab anno post Christum natum MCXCVIII ad annum MCCCXI*, 2 vols. (Berlin 1874-75). The complete registers of the popes of the thirteenth and fourteenth centuries are being published under the auspices of the École française de Rome. Modern bulls will be found in *Acta sanctorum sedis*, vol. i-xli (Rome 1865-1908), continued as *Acta apostolicae sedis*, vols. i-xx (Rome 1909-28). The concordats between the papacy and the various governments are collected in *Raccolta di concordati su materie ecclesiastiche tra la santa sede e le autorità civili* (Rome 1919); the volume, published anonymously, is by Angelo Mercati.

BULLER, CHARLES (1806-48), British parliamentarian and reformer. He was born in India and educated at Harrow, under the private tuition of Thomas Carlyle, and at Trinity College, Cambridge. In 1830 he succeeded his father as member of Parliament for a Cornwall pocket borough.

Influenced, in his earlier years at least, by the philosophy of Bentham, he was an advocate of parliamentary, poor law and other reforms. He rendered his greatest service, however, in the field of colonial affairs, in which he became interested about 1833. Taking advantage of the

opportunity offered by the Canadian crisis a few years later he became chief secretary of Lord Durham's mission of 1838. Lord Durham's memorable report has been attributed to Buller, although the latter disclaimed the story and the weight of evidence is against it. Buller did much, however, to secure the endorsement for its principles. He urged a liberal colonial policy and the control of emigration for the amelioration of conditions in the mother country and the development of overseas possessions. *Responsible Government for Colonies* (n. p. 1840, reprinted in Wrong), an anonymous pamphlet embodying reform doctrines, which is generally attributed to Buller, is important in the documentary history of the evolution of the British commonwealth of nations. At the time of his death he was the recognized parliamentary authority on colonial matters and was on the way toward a cabinet post.

W. A. ROBINSON

Consult: Wrong, E. M., *Charles Buller and Responsible Government* (Oxford 1926).

BULLIONISTS. The name "bullionists" is applied to a school of economic writers of the sixteenth century; they are sometimes called the "early mercantilists" but are in reality quite distinct. Their starting point was the importance assigned to bullion. Thus Clement Armstrong states ("A Treatise concerning the Staple [1530]," in Pauli, R., "Drei volkswirtschaftliche Denkschriften aus der Zeit Heinrichs VIII von England" in *Göttingen Gesellschaft der Wissenschaften Abhandlungen*, vol. xxiii, Göttingen 1878): "The hole wealth of the ream is for all our riche commodities to gete out of all other reamys therefor redly money." So in *Gemeine Stymmen von der Muntze* (Leipsic 1530) we read, "Reichtumb, das ist Gelt." The fullest statement is found in Milles, *The Customer's Apology* (n.p. [1601]): "Though money were the beames and exchange the very light, yet bullion is the sonne: though money were the ruddler and sterne of all our shipping, and exchange the compasse, yet bullion is the pilot: though money be the blood in the body trafficke, and exchanges the spirit, yet bullion is the chylus." In a later work, *The Misterie of Iniquitie* (London 1609), he says: "for as by goodnes men first become happy, both soveraignes and subjects, the same fixt in Bullion, makes men to be kings, and kings to be Gods."

In the endeavor to increase the stock of bullion the writers and statesmen were agreed on five measures: restriction on the import of

ephemeral luxuries; prohibition of the export of bullion, with the array of searchers, customers and comptrollers; the staple towns with their mints, coyners, hostlers and the like; the statutes of employment, providing that money received on sales of imports be "employed" on the purchase of native commodities; and official control of the exchanges.

These methods, designed to secure a surplus of bullion in each transaction, have happily been called by Jones ("Primitive Political Economy in England" in *Edinburgh Review*, vol. lxxxv, 1847, p. 426-52) the balance of bargain system. Vernadskii (*Ocherk istorii politicheskoi ekonomii* [Summary of the history of political economy], St. Petersburg 1858) suggests balance of exchange system. Another and more distinguished Russian, Ianzhul (*Angliiskaya Svobodnaya Torgovlya* [English free trade], 2 vols., Moscow 1876-82) prefers balance of money system. Heyking (*Zur Geschichte der Handels-bilanz-theorie*, Berlin 1880) likes balance of purchase system (*Kaufgeschäfts-bilanz-system*). But the usually accepted term is simply the bullionist system.

The first doctrine is found very early. In *The Libelle of Englyshe Polycye*, 1436 (ed. and tr. into German by W. Hertzberg, Leipsic 1878, English ed. by G. F. Warner, Oxford 1926) the Italians are blamed for bringin in "thinges of complacence, . . . apes and japes, . . . nilles and trifles that littel have availed" in return for which "they beer the golde out of this land and souketh the thrifte away out of our hand." In 1549 Hales (*A Discourse of the Common Weal of this Realm of England*, London 1581, ed. by E. Lamond, Cambridge, Eng. 1893) warns against exchanging "substantiall wares" for such trifles as "cardes, puppetes, toothepikes, broches, oringes and a thousand like thinges" for "thus we are impoverished of our treasure." Melchior von Osse in his *Testament* (ms. 1556, later ed. Halle 1717) decries the "Unnothdürfftige Wahre," for just as the leeches suck the blood "also sauget solcher unnützer Pracht das Gold." Malynes (*A Treatise of the Canker of England's Commonwealth*, London 1601) distinguishes between "thrifty" and "unthrifty" commodities; Roberts (*The Treasure of Traffike*, London 1641) between "needful wares" and "petty manufactories"; and as late as 1662 the author of *Short Notes and Observations in Point of Trade* (London 1662) calls attention to the import of "vain and unnecessary commodities."

It is interesting to observe that although

Francis Bacon, basing himself upon the super-scription of a report of 1615, seems to have been the first to use the term "balance of trade" (see his "Letter of Advice to the Duke of Buckingham" which was written in 1616, published in 1661 and reprinted in his *Letters and Life* ed. by Spedding, vol. vi, London 1872, p. 22-23, explaining that if exports exceed imports the balance of trade must be returned in money or bullion) he really agrees with the bullionists when he advises: "Let not the merchant return toys and vanities (as sometimes it was elsewhere apes and peacocks) but solid merchandize."

The leading English bullionist was Thomas Milles, a customs officer at Sandwich. In *The Customer's Apologie* he speaks wistfully of the old "orderly trafficke with its leges mercatorias, its courts of pields-pouldres, its staples and mints" and its statutes of employment. Nowadays with the new fangled "speculative kinde of men" it is as difficult to distinguish "a merchant from an usurer with their billes of exchange" as to tell "an English-Catholic-Christian" from a "Roman-Jewish-Jesuite." The consequence is that "customers are perplext" so that the king "wanting bullion, his money seemes to faile and his myntes can stamp no more." The new "particular companies and private societies" have "broken into the staples, prophan'd our soveraigne's munts, turn'd money into a merchandize, and undermin'd the state with usurie—and all for lack of staples."

John Wheeler, secretary of the Merchants' Adventurers, replied in *A Treatise of Commerce* (London 1601), warning the "backbiting customers" to stop discussing things "which either of ignorance they understand not the ground of, or through malice doe misconceive and misreport of." Milles responded in *The Customer's Reply, or Second Apologie* (London 1604), driving home the current abuses and printing the "Treatise of Exchange of 1564," mentioned below. A few years later he returned to the charge, issuing in 1608 *The Customer's Alphabet and Primer* (London 1608), in which he elaborated "the true pattern of a staple." Later in the same year he published *Acroamata for Bullion and Staples* (London 1608), following this in 1609 by *The Customer's Apologie, heere onely abridged, paraphrased and fitted unto the written Table or Epitome of all his other Workes Touching Trafficke and Customes* (n.p. [1609]). In 1610 he wrote the *Out-Port Customer's Account* and in 1611 he published his most elaborate work, *The Misterie of Iniquitie*. Emphasizing the "disorder of justice

commutative, for want of staples" he sums up: "no staples, no trafficke; no trafficke, no mines, no mines, no bullion; no bullion, no mints." Were "trafficke once but fixed" "our Bullion (without which no Kingdom can stand) shall be made currant money and our staples made perpetual mines." Thus can the monarch "cut the throat of that stayne and stay of piety, that contempt of equity, that baud of bankers; that art of witchcraft and mystery of iniquity (usury)" and take through the "staples, our first steppe towards heaven and our summum bonum."

Finally in 1619 he repeated his arguments in *An Abstract almost Verbatim (with some necessarie Addition) of the Customers Apologie written 18 yeares ago* [n.p., n.d.]. Although he now ruefully confessed that "my faith be but fraile, my spirits well-nie spent, and my credite almost gone" yet he is impelled "to wish and pray for staples as heartily as I can."

In order to understand these references to the mystery of the exchanges it is necessary to advert to the mediaeval monetary situation. After the gold coinage was introduced in the thirteenth century the European states were on a bimetallic basis. The continual discrepancies between the market and the mint ratios caused the export now of gold, now of silver. The endeavor to prevent this, coupled with the desire of the prince to exercise the lucrative prerogative of his "domain of money," led to repeated debasements, with a resulting rise of prices.

This concealed for a time the real explanation of the price revolution of the sixteenth century. The theory that this was due to the influx of the precious metals from America was first stated by Noël du Fail (*Les baliverneries, ou contes nouveaux d'Eutrapel*, Paris 1548, ed. by E. Courbet, 2 vols., Paris 1894); and was elaborated by Bodin (*Réponse . . . aux paradoxes de M. de Malestroit*, Paris 1566, tr. as *The Elements of Political Economy*, London 1858), whence it found its way into the 1581 edition of Hales' work, now published with the new title, *A Compendious or brieve Examination of certayne ordinary complaints*.

The other doctrine was the one which, since MacLeod gave it that name in 1858, has been known as Gresham's law. As a matter of fact, however, the generalization is not found in any of the pronouncements of Sir Thomas Gresham. What he states in the memorandum of 1559 is that the changes in the coinage projected by the queen would be followed by the export of the old money. When MacLeod subsequently ascertained that similar assertions had been

made before Gresham, he suggested (*The History of Economics*, London 1896) that it "ought in justice to be called the law of Oresme, Copernicus and Gresham." Unfortunately MacLeod's ignorance of mediæval literature caused him to overlook the fact that the statement was a commonplace even before Oresme, as with Pierre DuBois who pointed out ("De recuperatione terre sancte, 1305," in *Gesta Dei per Francos*, ed. by J. Bongars, Hanover 1611; also ed. by C. V. Langlois, Paris 1891) that debasements injure every one except the *firmarii* and *factores monetarum* who export the overvalued money.

When, however, for any reason tampering with the metal content of the coins seemed undesirable the theory arose that the best way to insure an abundance of bullion was to control the rate of foreign exchange. This took the form either of official valuation or of government monopoly. With the growing evasion of such laws by the private exchangers, continental literature of the fifteenth and sixteenth centuries concerned itself more and more with discussion as to what particular forms of the transactions fall within the prohibition of usury. In England, where the whole movement came later, the earliest treatment is found in "A Treatise of Exchange in Merchandise and Merchandising Exchange, 1564" (in Milles, *The Customer's Replie*, London 1604). "Lawful exchange" as carried on by the cambiadors is here distinguished from the other kind of exchange "when indeed it is not so, but a meer foeneration, and a making a ware and merchandise of money: that that is the same, and by the same, they buy and sell, rayse and abate the price of money, as of any other ware. Wherefore, it is not to be called simply exchange but properly the merchandizing of money or merchandizing exchange." The objection to this is stated as follows: "Forasmuch as money exchanged after this way must be payde againe according to the conditions and compacts and not according to the just and lawfull valuation it hath by public authority, the which temerarious alteration of public coynes is the principal foundation of the gaines, for the love and greediness whereof the other lawfull exchange is expelled the trade corrupted and (the reason) why all wares bear such excessive prices."

In Italy the chief upholder of official regulation was Marc Antonio di Santis (*Discorso intorno alli effetti che fa il cambio in regno*, Naples 1605). The three reasons which he advances for the scarcity of coin are the failure to pay for the exports in cash, the large imports of luxuries and

above all the profits in exchange. The remedy consists in enforcing the "prammatica," or prohibition of any deviation in the rate of exchange from the official par. In England we find the further step of insistence on a government exchanger. The leading exponent of this was Gerrard de Malynes. In *A Treatise of the Canker of England's Commonwealth* he contends that the private manipulation of the exchanges "is become predominant or doth overrule the course of commodities and money," thus leading to "an overballancing of forraigne commodities with our home commodities, which to supply or counter-vaille draweth away our treasure." The remedy lies in the appointment of "certain skilful and substantiall men to be the generall exchangers." In *St. George for England* (London 1601) the two wings of this dragon to be vanquished are declared to be *usura palliata* and *usura explicata* of the exchanges. In *Englands View in the Unmasking of Two Paradoxes* (London 1603) he gives a full version of Bodin's discussion, contending, however, that a more important paradox is concerned with the comparison of home and foreign prices, and maintaining that there would be no "over-ballancing of forreine with our home commodities" if "the course of exchange for money did not over-rule the property of money."

The general argument was developed by Sir Robert Cotton (*The Manner and Means how the Kings of England have from Time to Time supported and repaired their Estates*, London 1609; reprinted in his *Cottoni posthuma*, ed. by J. Howell, 3rd ed. London 1679). He holds that the king should enforce his old "Regalitie of Coine and Bullion" and reestablish the "*cambium regis*, his own exchanger." In Culpeper, *A Tract against Usurie* (London 1621), it is again contended that the "Merchants who send over bills of exchange eate us out with our money." The same position is taken by the author of *Cambium Regis; or, the Office of his Maiestie's Exchange Royall* (London 1628), in which the evil practises of "exchanging goldsmiths" are contrasted with the "loyall and legall price of Bullion" effected by the king's exchanger. The last defender of the system is Ralph Maddison (*Englands Looking In and Out*, London 1640), who pronounces the "merchaunt exchange" "very deceivable and damageable" and makes the real "ballance of trade" depend on "every particular trade" so that "their walke being observed, it may be known which trade bringeth in or forceth in money."

The opposition to the bullionist doctrine was first voiced on the continent. In France Barthélemy de Laffemas pointed out in *L'incrédulité ou l'ignorance de ceux qui ne veulent cognoistre le bien et repos de l'estat* (Paris 1600) that the evils of the "changes and rechanges" can best be remedied by the "police and controlle" involved in the protection of native industry and the prohibition of foreign goods. In *Comme l'on doit permettre la liberté du transport de l'or et de l'argent hors du royaume* (Paris 1602) he shows the futility of the bullionist regulations and contends that the only way to prevent the export of coin is to develop home manufactures.

In England the criticism of the export prohibition came later, although at various times certain government advisers had cast doubt on the practise, as long as exports exceeded imports. So in the commission of 1381 (Ruding, Rogers, *Annals of the Coinage of Great Britain and its Dependencies*, 3 vols., 3rd ed. London 1840, vol. i, p. 239-43), in the memorandum of 1549, "Policies to Reduce this Realme . . . unto a Prosperous Wealth and Estate" (*Tudor Economic Documents*, ed. by R. H. Tawney and E. Power, 3 vols., London 1924, vol. iii, p. 311-45) and again, shortly afterwards, in the *Considerations for the Restraining of Transportinge Gould out of the Realme* (Schanz, Georg, *Englische Handelspolitik gegen Ende des Mittelalters*, 2 vols., Leipzig 1881, vol. ii, p. 648-49). This last expounds the *causa causarum* of bullion exports and contends that "if England would spend lesse of foreyne comodities the remaine must of necessity be retored of silver or gould." But the real discussion began with the shipwreck in 1613 of an East Indian company's ship carrying a large amount of bullion. J. R. in *The Trades Increase* (London 1615) now exclaimed, "Let the whole land murmure at the transport of treasure." This brought forth the rejoinder of Dudley Digges, a director of the company, who in *The Defence of Trade* (London 1615) upholds the export of bullion. A similar defense was made a few years later by Mun in *A Discourse of Trade from England unto the East-Indies* (London 1621) which, however, still praises the statutes of employment. Finally in *The Petition and Remonstrance of the Governor and Company of Merchants of London, trading to the East Indies* (London 1628), written by Mun, it is claimed that the export of bullion is "the best trade and meanes we have to increase our Treasure."

The bullionist doctrine of the exchanges was also first refuted on the continent. Antonio Serra

(*Breve trattato delle cause che possono far abbondare li regni d'oro e argento*, Naples 1613) answered de Santis' arguments one by one, declaring the true cause of the outflow of bullion to be found in the excessive imports of foreign wares. For real wealth consists (p. 30) in the surplus of goods (*sopraabbondanza della roba*), which can be brought about only by favoring home industry. In England the transition came a little later. It is true indeed that business men had opposed the practise at various times. So Sir Richard Graham urged in 1531 that private merchants be permitted to exercise "exchanges and rechanges"; and in 1576 the Italian merchants protested against the reestablishment of the public exchange office (printed in Schanz, Georg, *Englische Handelspolitik*, 2 vols., Leipzig 1881, vol. ii, p. 642-46). But the first real discussion in England came in 1622. In that year Edward Misselden published *Free Trade; or, the Means to make Trade Florish* (London 1622), in which he found the lack of money to be due to the undervaluation of the coin, and still maintained a belief in the efficacy of the prohibition of bullion exports. Malynes now reentered the lists with *The Maintenance of Free Trade according to the Three Essentiall Parts of Traffique, namely Commodities, Money and Exchange of Moneys by Bills of Exchanges for other Countries* (London 1622), in which he catalogued the twenty-four "admirable feats to be all done by exchange" and advanced thirty-five remedies culminating in the "Kings Royall Exchanger." He followed this in the same year with his *Consuetudo vel Lex Mercatoria* (London 1622) with an elaborate development of the same thesis. Misselden replied with *The Circle of Commerce; or, the Ballance of Trade in defence of Free Trade: Opposed to Malynes Little Fish and his Great Whale* (London 1623), in which he for the first time in any book used this phrase and, now abandoning his earlier views as to the export of bullion, claimed that "it is not the rate of exchange, but the plenty or scarcity of commodities" that is responsible for price changes and the export of bullion. Despite the retort by Malynes (*The Center of the Circle of Commerce; or, a Refutation of a Treatise intituled The Circle of Commerce*, London 1623), in which the doctrine of the balance of trade is declared to be "full of deceitfull fallacies" (p. 137), the new theory gradually won the day and after the crushing refutation by Mun (*England's Treasure by Foreign Trade; or, the Ballance of our Foreign Trade is the Rule of our Treasure*, London 1664; reprinted in the Economic Classics series,

New York 1895) we hear no more of the "admirable feats of the exchangers." Moreover with the acceptance of the newer doctrines the bullionist distinction between "thrifty" and "unthrifty" commodities was replaced by the distinction between raw materials and manufactured goods, which was henceforth to play so great a role in the balance of trade doctrine.

Despite their inadequate theories the bullionists were in one sense the earliest modern economists. The mediaeval writers, under the lead of the theologians, the Glossators and the canonists, dealt primarily with problems of individual morality, typified in the usury controversy. The bullionists were the first to stress questions of national or social wealth and to develop monetary theory from the prince's prerogative of debasing the coin to the wider discussion of the relation between money and prices as well as the connection between bullion and social prosperity. In this way they paved the way for the mercantilists

EDWIN R. A. SELIGMAN

Consult: There is no satisfactory account of bullionist theory. A few disconnected statements will be found in Cunningham, William, *The Growth of English Industry and Commerce in Modern Times*, 3 vols. (5th ed. Cambridge, Eng. 1910-12) vol. II; Unwin, George, *Studies in Economic History*, ed. by R. H. Tawney (London 1927); and R. H. Tawney's introduction to Wilson, Thomas, *A Discourse upon Usury* (London 1925) p. 1-15. For a statement of the theory of the exchanges see Endemann, Wilhelm, *Studien in der romanisch-kanonischen Wirtschafts- und Rechtslehre*, 2 vols. (Berlin 1874-83). Some of the continental writers are discussed in Bodin de Saint-Laurent, Jean de, *Les idées monétaires et commerciales de Jean Bodin* (Bordeaux 1907); Laffitte, Paul, *Notice sur Barthélemy Laffemas* (Paris 1877); Fornari, Tommaso, *Studi sopra Antonio Serra e Marco Antonio de Santis* (Milan 1880). For Malynes and Misselden see Seligman, E. R. A., *Curiosities of Early Economic Literature* (p.p. San Francisco 1920). The English legislation is described in Jones, Richard, "Primitive Political Economy of England" in his *Literary Remains* (London 1859) p. 291-335, with a passing mention of Milles and Misselden, whom he had obviously never consulted.

BULMERINCQ, AUGUST VON (1822-90), German jurist. He was professor of international and public law, becoming eventually the successor of Bluntschli at Heidelberg. Before 1870 there had been little progress in international law in Germany and the work of Heffter with its insecure foundation in the law of nature ruled the field. Better acquainted than any of his contemporaries with the international law of all

nations, especially as embodied in European international treaties, Bulmerincq was well equipped to become the leader of a new positivism.

Bulmerincq made his reputation with his *Die Systematik des Völkerrechts von Grotius bis auf die Gegenwart* (Dorpat 1858). He objected that too little attention had been paid to the systematic exposition of international law since Grotius, which had come to be artificially divided into two parts, "Law of Peace" and "Law of War." Bulmerincq sought to accomplish its systematization upon the analogy of private law, dividing it into substantive and adjective international law. His program of positivism was developed theoretically in his *Praxis, Theorie und Codification des Völkerrechts* (Leipzig 1874) and *Das Völkerrecht oder internationale Recht* (Freiburg 1887, 2nd ed. 1889; previously published in the *Handbuch des öffentlichen Rechts der Gegenwart in Monographien*, vol. i, pt. ii, 1884). The specific field in which Bulmerincq himself exemplified his method was mainly that of the maritime law of war, particularly the law of prize. His general ideas were developed more logically by his pupil Bergbohm who, indeed, criticized his master for the traces of natural law which were still to be found in his work.

WILLIAM SEAGLE

Consult: Bergbohm, Karl M., in *Allgemeine deutsche Biographie*, vol. XLVII (1903) 348-50; Rivier, A., in *Handbuch des Völkerrechts*, ed. by F. Holtzendorf, 4 vols. (Berlin 1885-89) vol. I, p. 491-93 and further references there cited.

BÜLOW, BERNHARD HEINRICH MARTIN, PRINCE VON (1849-1929), the fourth chancellor of the German Empire. Born of an ancient and distinguished Prussian family, he filled various diplomatic posts at Vienna, Athens, Bucharest and Rome. In 1897 he became secretary of state for foreign affairs and in 1900 succeeded Hohenlohe as chancellor, a difficult position which he filled for nine years.

Under Bülow's guidance Germany definitely entered the sphere of *Weltpolitik*. Because he and his adviser, Holstein, believed that England could be brought to make greater concessions, that she would never come to a friendly understanding with France or with Russia and that Germany could therefore continue to enjoy the position of *arbitrator mundi*, he failed to take up more cordially the proposals of Joseph Chamberlain for an Anglo-German alliance. It is

doubtful, however, whether such an alliance could have been brought about at the time in view of the mutual antagonism arising from South African, commercial and naval questions and because of the opposition of Lord Salisbury and a majority of the British cabinet. After the Anglo-French Moroccan Agreement of 1904 Bülow and Holstein sought to defend Germany's Moroccan interests by a policy of intimidation toward France. To break up the Anglo-French friendship the kaiser at the same time attempted an alliance with Russia by means of the Björko treaty (1905), which was later repudiated by the czar.

In 1908 Bülow's carelessness permitted the publication in the London *Daily Telegraph* of an indiscreet interview with the kaiser which raised a storm of criticism in both England and Germany. Bulow took the blame upon himself but his Reichstag speech on the subject offended his imperial master, who became thenceforth less cordial to him. Bulow also differed with the kaiser and von Tirpitz in his desire to restrict Germany's naval program. In addition, the dissolution of the Reichstag bloc, which included all the parties except the Center and the Social Democrats, led to the rejection of Bülow's budget and he resigned in 1909. After the outbreak of the World War Bülow was sent again as ambassador to Italy in an effort to keep Italy neutral, but was unsuccessful.

In versatility Bülow was second only to Bismarck. Nevertheless he piloted the ship of state into dangerous currents. Clever and self-reliant, he was handicapped by the flippant habit of obscuring the truth in amusing metaphors and by an assumed optimism which silenced healthy criticism of his policies. He presented a brilliant apoloia in his *Deutsche Politik* (Leipsic 1914, 2nd ed. Berlin 1916; tr. by M. Lewenz as *Imperial Germany*, rev. ed. New York 1917) and before his death prepared his memoirs for publication. His speeches were collected by J. Penzler and O. Hoetzsch (3 vols., Leipsic 1903-09).

BÜLOW, OSKAR (1837-1907), German jurist. Bülow was professor of civil procedure at the universities of Heidelberg, Giessen, Tübingen and Leipsic. His importance, however, rests upon his leadership in the school of German jurists who, as representatives of the reaction against the earlier historical school, regarded German civil procedure as an independent branch of German public law. Until the end of the seventies civil procedure had been largely concerned with the old Roman-Italian law of process which Germany had taken over during the Middle Ages and developed further in its legal practise. With the unification of the judicial system and the formulation of a civil code for the whole empire in 1877 German legal science turned to the dogmatic development of the prevailing statute law as the almost exclusive subject of jurisprudence.

Together with Adolf Wach, Bülow was of outstanding prominence in the new movement. His first work, on the maintenance of actions, deals with the public law basis of civil procedure. Of his later books the brief study *Gesetz und Richteramt* probably exercised the greatest influence. Here Bülow demonstrated that even the system of codified statute law afforded the judge a field of action as creative as that of the legislator. This was the basis of a higher evaluation of the judicial opinion even under the modern system of codification.

BUNDES-RAT in Germany was created in accordance with the constitution drafted by Bismarck for the North German Confederation (1866-71) and retained its power and functions with the establishment of the empire. It was intended as a substitute for the Bundestag, which in the period between the Congress of Vienna and the Austro-Prussian War was the supreme organ of the loose confederation of German states.

The Bundestag, which met under Austria's chairmanship, had its permanent seat in Frank-

fort. Of its seventeen members eleven represented the same number of larger states and six were delegated by curias, in which the smaller states and free cities were grouped for the purpose. For the rendering of important decisions the Bundestag was expanded into the Bundesversammlung, with sixty-nine members. In neither body was the apportionment of seats proportional to the population or size of the member states, which included not only German states and principalities but also Denmark, because of its sovereignty over Holstein, and the Netherlands, as the ruler of Luxemburg; in addition there was until 1837 a representative of the English sovereign, who governed Hanover by virtue of a dynastic union. The competence of the Bundestag was very limited because each member of the confederation enjoyed complete sovereignty, including the right to enter alliances in so far as they did not militate against the confederation. In some cases—for instance in Austria and Prussia—its authority extended only to parts of the member states. Consequently the Bundestag was not important in German political development; for example, the Zollverein was established without its assistance or sanction. Neither did it enjoy any popularity, particularly because it was associated with measures against the liberal, nationalist movement. Its existence was terminated by the war of 1866.

The Bundesrat, the organ of the governments federated in the German Empire, embodied the sovereignty of this state. Its membership was appointed by the governments, so that it resembled a permanent council of ambassadors rather than an elected legislature. The representation of the constituent states followed in some measure the practise of the Bundestag. Prussia had 17 seats, Bavaria 6, Saxony and Württemberg 4, Baden and Hesse and (after 1911) Alsace-Lorraine 3, Mecklenburg-Schwerin and Brunswick 2, and the remaining seventeen states one each. It was due to Bismarck, who attempted to allay fears of Prussian hegemony, that Prussia, with two thirds of the empire's population, had only 17 of the 61 votes. Constitutional provisions, however, made Prussian consent imperative for every law on financial, military and economic questions; moreover no change in the constitution could be made against an opposition of 14 votes. Prussia held the presidency of the Bundesrat and the imperial chancellor or his deputy presided over its sessions, which were not public.

It met on the call of the emperor, who as king of Prussia appointed the Prussian delegates. The appointments were political in character and the delegates were responsive to every wish of their home governments; the votes of each member state were always delivered as a unit.

The authority of the Bundesrat was threefold: legislative, administrative and judicial. Every state had the right of legislative initiative and the body was divided into committees to prepare legislation. Coordinate in legislative activity with the Reichstag and the emperor, the Bundesrat customarily initiated all important legislation; it also prepared the annual budgets. It had the right to disapprove amendments made by the Reichstag, but if it endorsed them the emperor was bound to accept the law. Members of the Bundesrat had the right to be heard in the Reichstag. Indirectly the Bundesrat was extremely influential in administration, which was almost entirely in the hands of the constituent states. It developed upon the Bundesrat to elaborate and issue executive regulations and general administrative orders to insure uniform practise. As a judicial body it was empowered to act in cases of disagreement between the empire and a state, between constituent states and in constitutional conflicts within a state. It could delegate decision to a supreme court. It also enjoyed important powers in the purely political sphere. Except for such contingencies as the danger of an immediate offensive against national territory its consent was required to declare war. Likewise treaties with foreign countries had to be ratified by the Bundesrat. It determined upon measures against any of the federated states and its consent was necessary to dissolve the Reichstag and proclaim new elections.

The German Bundesrat was thus a body combining the powers of a second chamber, a council of state and a supreme court. It was the agency through which Prussia exercised its supremacy in a federation of apparently equal states. The relatively unchanging character of its membership strengthened the position of the Bundesrat in both theory and practise. It was the chief constitutional bulwark of the conservative and monarchist forces in Germany. It was essentially different from the Bundesrat of Austria and that of Switzerland, which are primarily legislative bodies. Similarly the Reichsrat, which succeeded the Bundesrat in republican Germany, is merely a legislative

body representative of the federated states, on an equal footing with the Reichstag.

BUNGE, CARLOS OCTAVIO (1875-1918), Argentine jurist, educationist and publicist. His doctoral dissertation, *El federalismo argentino* (Buenos Aires 1897), attracted considerable attention because of its sociologico-historical interpretation of Argentine public law and political institutions, after the manner of Alberdi, Sarmiento, Spencer and Taine. In 1901 he published *El espíritu de la educación* (Buenos Aires; best known as *La educación*, from the second edition, Madrid 1902). In this work and in his teaching as professor of education at the University of Buenos Aires (1905-18) he treated his subject as a social science, emphasizing the philosophy of the history of education, and educational sociology rather than pedagogy. In 1903 appeared his *Nuestra América* (Barcelona) and *Principios de psicología individual y social* (3 vols., Madrid; also translated into French); the former, an essay in social psychology after the manner of Le Bon and Tarde, being one of the most widely read interpretations of Latin American history and politics, and the latter, the first Argentine attempt at a systematic treatise on social psychology. Perhaps the most successful of his works, *Teoría del derecho, principios de sociología jurídica* (Buenos Aires 1905; best known as *El derecho*, from the second edition, 2 vols., Buenos Aires 1907; translated also into Italian and French), was like all his works strongly sociological in outlook and method. His *Casos de derecho penal* (Buenos Aires 1911) and *Historia del derecho argentino* (2 vols., Buenos Aires 1912-13) practically complete his studies in legal philosophy and history. Bunge, a voluminous writer, left among various biographical and literary studies two biologico-sociologi-

cal works of fiction, *La novela de la sangre* (Madrid 1903) and *Viaje a través de la estirpe y otras narraciones* (Buenos Aires 1908). Although he was neither particularly original nor always accurate or profound, he was among the most active in his generation in Argentina in introducing socio-psychological conceptions into the philosophy of law.

BUNGE, FRIEDRICH GEORG VON (1802-97), Baltic jurist and historian. He was the first to edit systematically the sources of mediaeval Baltic history and to codify the Baltic private law. Each of the three Russian Baltic provinces, Livonia, Esthonia and Courland, had its own law, based originally upon German customs but displaying characteristic variations caused by the differences in the autonomous development of the provinces. The law had never been codified and there were no standard rules of interpretation. Bunge investigated the sources and history of the existing law, and sought to establish the relations between the development of the law and the political and social conditions of the several provinces. While engaged in this study he conceived the project of a complete collection of Baltic historical documents and records up to 1561, and to this end he started in 1853 in Reval the *Liv- est- kurländisches Urkundenbuch*, of which he edited the first six volumes. This work inaugurated a new era for historians of the Baltic territories. The Russian government entrusted him with the codification of the Baltic private law, a work on which he was engaged from 1856 to 1864. The code was sanctioned by the czar in 1865.

BUNGE, NIKOLAY CHRISTIANOVICH (1823-95), Russian economist and statesman. He graduated from the University of Kiev in

1845, served as professor of economics, statistics and administrative law (interpreted as economic policy) at the same university from 1850 to 1880 and was elected a member of the Russian Academy of Sciences in 1890. His career in public life was not less distinguished: he was a member of the commission which prepared the financial measures connected with the emancipation of the peasants; he was several times rector of the University of Kiev; and after 1865 he was in charge of the Kiev branch of the State Bank. In 1880 he was appointed assistant minister of finance and in the following year, with the resignation of the liberal members of the government after the assassination of Alexander II, became minister of finance, an office which he held until 1886. In the last decade of his life he was president of the Committee of Ministers, a council which passed on all matters exceeding the competence of a single ministry and sometimes on measures of an urgent legislative character.

Bunge modernized considerably the Russian system of taxation. He abolished the salt excise and the poll tax paid by the lower classes and considerably reduced the redemption payments of peasants inaugurated as a result of their emancipation. On the other hand he introduced a tax on moneyed capital and increased the taxation of business enterprises, measures regarded as forerunners of a general income tax. He instituted the system of tax inspectors and thus created for the first time in Russia an organization devoted exclusively to tax administration. He took the first steps in preparing the monetary reform carried out under Vishnegradsky and Witte. Having definitely rejected the idea of raising the value of the monetary unit, he adopted the plan of monetary stabilization at the current level. He began the accumulation of a gold fund and advocated the legalization of private dealing in gold. Bunge also promoted labor legislation in Russia and introduced the system of factory inspectors.

Bunge's scholarship was not particularly forceful or original. As early as the fifties he appeared as a staunch exponent of the historical approach in theory and of liberalism in economic policy. Clearly influenced by the older German historical school, he became in his turn the founder of the Kiev school, which criticized the labor theory of value and opposed all forms of state intervention. As a statesman Bunge remained true to the views which he professed as a scholar. He was much less favorably disposed to

protectionism than his successors and in an official memorandum on the peasant question (1894) took a definite stand against the reactionary laws of 1893 and 1894 which strengthened the village community form of land tenure. Among the published works of Bunge important contributions are to be found not in general treatises or textbooks but in shorter writings dealing with questions of economic policy. Of these the more interesting are: an article on Russian currency including a program of financial reform (in *Sbornik gosudarstvennikh znaniy*, vol. viii, 1880, p. 86-127), a review of A. I. Chuprov's work on railway economics containing an exposition of Bunge's economic philosophy (*Izvestiya Evropy*, 1876, vol. ii, 314-52) and a monograph on the Russian salt excise (St. Petersburg 1893). Some of his essays on the history of economic doctrines appeared in a French translation as *Esquisses de littérature politico-économique* (Geneva 1898); this book contains a biography of Bunge by Kartavtsov and a bibliography of Bunge's works.

PETER STRUVE

BUONARROTI, FILIPPE MICHELE. See BABOUIVISM.

BURCHARD OF WORMS, eleventh century canonist. He was educated at the cloister school of Lohles and in the year 1000 was promoted to the bishopric of Worms by Otto III. Between 1012 and 1022 he compiled his *Decretum* (reprinted in J. P. Migne's *Patrologia latina*, vol. cxi, cols. 538-1090), the last and most important collection of canon law texts before the Hildebrandine reform party became dominant in the church. Although many collections were utilized, more than half of its 1785 texts were borrowed from the earlier collection of Regino of Prüm and the ninth century Italian collection known as *Anselmo dedicata*. A few texts affirm that secular enactments are subject to the law of God, but little else is included of a political character. Burchard's own texts are mainly upon the administration of penance.

Burchard's collection formed the most widely used corpus of canon law for almost a century until superseded by the collections of Ivo of Chartres. It was, however, unsatisfactory to the reformers because it did not sufficiently emphasize the primacy of the Roman See and because it compromised with prevailing practices in the matter of marriage of the clergy, investiture, dissolution of marriage and trial by ordeal. Near

the close of his bishopric Burchard promulgated (1023-25) one of the earliest municipal law books, the *Lex familiae wormatiensis ecclesiae* (reprinted in *Monumenta Germaniae historica*, Legum sectio iv, vol. i, p. 639-44), intended to supply a code for the administration of justice in secular affairs among the vassals of his bishopric.

M., *Burchard 1 von Worms und die deutsche Kirche seiner Zeit* (Munich 1905); Fournier, Paul, "Études critiques sur le décret de Burchard de Worms" in *Nouvelle revue historique de droit français et étranger*, vol. xxxiv (1910) 41-112, 213-21, 289-331, 564-84, and "Un tournant de l'histoire du droit 1060-1140" in *Nouvelle revue historique de droit français et étranger*, vol. xl (1917) 129-80, and "Le décret de Burchard de Worms, ses caractères et son influence" in *Revue d'histoire ecclésiastique*, vol. xii (1911) 451-73, 670-94.

BURCKHARDT, JACOB CHRISTOPH (1818-97), Swiss historian. He came of an old Basel family and received a humanistic education, first studying theology at Basel, then history under Ranke at Berlin and history of art under Kugler at Bonn. From 1844 to 1893 he taught with distinction at the University of Basel. Burckhardt's early works, which deal particularly with German history and history of art, show a strong culture-historical trend and reveal the impress of German romanticism. The fact that he had lived through the revolutionary period of 1830-48 strongly influenced his historical-political judgment.

Burckhardt's major historical works constitute a complete study of the development of the European culture that started with the Greeks. *Griechische Kulturgeschichte* deals with the genesis, nature and development of Greek culture and its relationship to contemporary religious, political and social forces. *Die Zeit Constantins des Grossen* describes the disintegration and decay of ancient culture and explains the triumph of Christianity over late antiquity and the transition to the Middle Ages. Finally *Die Cultur der Renaissance in Italien* portrays the rebirth of antiquity in humanism and the Renaissance and its fusion with the Italian folk spirit in subduing mediaevalism and in inaugurating the modern era. He draws a sharp contrast between the corporate character of mediaeval society and the strong individualism so characteristic of the Renaissance. Burckhardt had now the classical viewpoint and in these brilliant works he showed the strength, the continuity,

the multiple changes and forms of the human spirit which first attained sovereignty among the Greeks. With this approach he revealed himself as a late disciple in the school of Schiller and Goethe, representing for the nineteenth century the stronghold of humanistic idealism.

Burckhardt's works on the Renaissance greatly stimulated research and amounted to a virtual discovery of the period that was crucial for modern Europe. His epoch making studies in the art of the Renaissance are contained chiefly in *Der Cicerone*, *Geschichte der Renaissance* and *Beiträge zur Kunstgeschichte Italiens*. His idealistic conception of art, which he derived from the Greeks, led him to give first place to the Italians in the history of European art and his judgment had a tremendous influence upon aesthetic opinion from 1860 to 1900.

His philosophy of history, which combines a profound idealism with an intense pessimism, appears in concentrated form in his posthumous works, *Weltgeschichtliche Betrachtungen* and *Historische Fragmente*. Burckhardt was severely critical in his attitude toward the political, economic and social forces of his day and was in many respects closely akin to Nietzsche, upon whom he exerted a marked influence. He was antidemocratic, antirevolutionary and antimaterialistic—a spiritual aristocrat, an idealist and on the whole inconsistent with the spirit of the times. In the historical thought of the nineteenth century his works are among the most profound and their influence continues even in present day political history and thought.

BURDETT, FRANCIS (1770-1844), English political reformer and philanthropist. First elected for Boroughbridge in 1796 he continued in the House of Commons almost uninterruptedly until his death, representing Westminster for thirty years (1807-37). In the early part of his career his stalwart championship of parliamentary reform, of popular rights and liberty of speech as well as his opposition to war with France made him the most popular political figure of London. His protest against the action of the government in the Manchester massacres led in 1810 to his detention in the Tower of London and his imprisonment in a common jail. Because of Burdett's vigor and wide popular appeal Bentham, Place, Cobbett and other radicals of the day turned to him to sponsor in the House of Commons resolutions calling for specific reforms. Nevertheless his turbulent nature and the intricate cross currents of the reform movement led to many ruptures in his relationships with the leaders of various groups.

It was distinctive of Burdett's attitude and perhaps the secret of much of his parliamentary influence that he based his claims always on ancient constitutional and legal principles, in this respect following Horne Tooke whose disciple he was. After the passage of the Reform Act of 1832 his interest in democratic movements waned and he ended his political career as a Tory. Throughout his life he contributed munificently to many public and philanthropic projects including, among others, the Mechanics' Institute.

W. H. DAWSON

Consult: Hazlitt, William, in *The Spirit of the Age* (London 1825; reprinted in *Collected Works*, London 1902-04, vol. iv, p. 324-25); Halévy, Élie, *La formation du radicalisme philosophique*, 3 vols. (Paris 1901-04), tr. in one volume by M. Morris (New York 1928) p. 249-64; Wallas, Graham, *Life of Francis Place* (rev. ed. London 1918) chs. II and IV.

BUREAU, PAUL (1865-1923), French sociologist. He was one of the most prominent representatives of the school of sociology which aims at the study of contemporary social institutions by the Le Play method of first hand observation. After traveling in England, the United States and Norway, Bureau first became known for his monographs on particular institutions in those countries: *Le homestead, ou l'insaisissabilité de la petite propriété foncière* (Paris 1895); *L'association de l'ouvrier aux profits du patron et la participation aux bénéfices* (Paris 1898); *Le contrat de travail et le rôle des syndicats*

professionnels (Paris 1902); and "*Le paysan des fjords de Norvège*" in *La science sociale*, n. s., vols. xx-xxi, nos. 20-21 (Paris 1905-06). In *La crise morale des temps nouveaux* (Paris 1907) he added to the Le Play method an ideological approach which sought the causes of French immorality in the intellectual currents of the day. His *L'indiscipline des mœurs* (Paris 1920; English translation, *Towards Moral Bankruptcy*, London 1925) put him in the forefront of those who, while accepting Malthus' population formula, took a primarily moral view of the population question and sought a remedy in the strengthening of family ties and in continence within marriage. In his last work, *L'introduction à la méthode sociologique* (Paris 1923), Bureau outlined the general principles of the method of personal observation in sociology, and defined the task of this method as that of furnishing the material on which the art of social reconstruction is to be based.

PAUL GEMÄHLING

Consult: Lanza de Laborie, S. de, and others, *Paul Bureau* (Paris 1924).

BUREAUCRACY is the term usually applied to a system of government the control of which is so completely in the hands of officials that their power jeopardizes the liberties of ordinary citizens. The characteristics of such a regime are a passion for routine in administration, the sacrifice of flexibility to rule, delay in the making of decisions and a refusal to embark upon experiment. In extreme cases the members of a bureaucracy may become a hereditary caste manipulating government to their own advantage.

Until quite modern times bureaucracy seems to have arisen as a by-product of aristocracy. In the history of the latter a disinclination on the part of the aristocracy for active government has in some cases led to the transfer of power into the hands of permanent officials. In other cases the origin of bureaucracy may be traced to the desire of the crown to have a body of personal servants who may be set off against the appetite of the aristocracy for power. In the latter event the bureaucrats themselves may have developed into an aristocracy, as happened in eighteenth century France. Previous to the nineteenth century bureaucracies have always sought, wherever possible, to become a privileged caste. When they have succeeded they have attempted to obtain for themselves either the same powers as the aristocracy or access to

that superior class. In any case it was fairly characteristic of bureaucracies before the French Revolution not to consider the interests of the state as a whole. A notable example of this selfishness is the attitude of the French bureaucracy in the seventeenth and eighteenth centuries to the *vénalité des charges*; even so liberal minded a thinker as Montesquieu was prepared to defend the sale of offices in a monarchy (*Esprit des lois*, bk. v, ch. xix). Yet it resulted inevitably in a complete blindness to ability as a test for office. Even in quite modern times the Foreign Office of Great Britain has been very largely maintained as an appanage of the aristocracy; it was not until 1919 that applications for admission were entertained from candidates who did not possess a private income.

The advent of democratic government in the nineteenth century overthrew in the western world the chance of maintaining a system whereby officials could constitute a permanent and hereditary caste. But for the most part the new conditions which accompanied democracy made bureaucracy possible in a new phase. It was essential to have a body of experts surrounding the minister in charge of a particular service. The latter was an amateur who remained in office for at most a few years. It was therefore almost a condition of successful administration that the officials who surrounded him should hold office permanently. And since democracy implied also publicity, it was important too that there should be a uniform body of precedents, a consistent tradition, to which reference could be made in order to justify before a legislative assembly the action that was taken.

The tendency accordingly has been a certain suspicion of experimentalism, a benevolence toward the "safe" man. There develops almost insensibly an esprit de corps with canons of conduct, observance of which becomes the test of promotion. Administrative codes grow up and are applied simply from the conservatism of habit. When rules have been long in operation or when they have been made by men of considerable experience it is very difficult to resist their authority. Because they are old it is held that they embody necessary experience; and officials are not easily persuaded to abandon them. A bureaucracy, moreover, because it is open to public criticism in a democratic state is always anxious to secure a reputation for accuracy. It prides itself on not making mis-

takes. It insists on seeing questions from every point of view. This results not seldom in a slowness in taking action, a multiplication of *paperauserie*, in which the negative side of some proposed course of action is easily magnified as against its possible advantages. Because mistakes will lead to criticism a bureaucracy is easily tempted to persuade a timid minister that the statute he contemplates is probably destined to fail.

Under modern conditions these problems are magnified still further. The scale of the modern state and the vastness of the services it seeks to render make expert administration inevitable. To control the expert in such conditions is an unenviable task. The necessary knowledge of detail is as a rule concentrated in his department alone. The need to be impersonal means uniformity of administration; and this in its turn means a code of precedents through which it is difficult to cut one's way to the recognition of a new principle. Experts, moreover, naturally tend to push the field they administer to its furthest confines; the appetite for power grows by what it feeds on. In England, for example, the last thirty years have seen the increasing abandonment by Parliament of any effective control over departmental action. Even judicial control has had to surrender to the need for administrative discretion rendered necessary because the processes of law are too cumbersome to deal effectively with the delicacy of the technical issues involved. Where the legislative machinery still attempts interference, as in the United States, the result is fatal to expert and adequate administration.

We have reached, in short, a position in which certain simple principles may be laid down. (1) In countries built upon the English parliamentary model the legislature cannot because of the extent and pressure of its business do more than accept or reject the conclusions of ministers. (2) The conclusions of ministers based, as they must be, upon information which requires experts for its formulation and interpretation are very largely those of the higher officials of the departments in their charge. (3) In the department there is a constant pressure toward caution. The minister has to assume responsibility for the mistakes of his subordinates and it is a point of honor with his subordinates that these be minimal; the simplest way to this end is to minimize the sphere of novelty. (4) The system of appointment by competitive examination, adopted as a necessary

precaution against the evils of patronage, means that the young official grows up in the department and that his promotion depends largely upon the recommendation of his seniors. In this sense a high reward may too easily be won for conformity to the departmental code. In any case appointment from without is deeply resented and it will be found that most officials favor promotion by seniority; this, as a rule, is to mistake antiquity for experience. (5) In the United States there is hardly a bureaucracy in the European sense of the term; the small salaries and the operation of the spoils system prevent the continuity of service known in Europe. But the disadvantages of this system are great: the failure to attract able men to the civil service and the consequent low level of quality in the administrative performance. Discontinuity at the top of the departments involves a price perhaps even heavier than that paid for excessive continuity.

It should be pointed out that these undesirable characteristics of bureaucracy are not in the least confined to the service of the state; they operate wherever there is large scale organization. Trade unions, churches, institutions for social work, great industrial corporations, all these are compelled by the very size of the interests they represent and by their complexity to take on the same habits of bureaucracy. The familiarity of officials with the technical details of their work involves the accretion of power in their hands. The need for rules makes for stereotyped regulation. Innovation is distrusted because it means a departure from the wonted routine. The problem, for example, of influencing a great political party to adopt a new outlook frowned upon by its leaders; the effort to persuade, say, a great shipbuilding firm to turn from iron to steel; the difficulty of inducing case workers in a charitable organization to skepticism of their inquiries; these are merely examples of the power of habit over those who specialize in a particular department. It is rarely difficult in a trade union congress for the officials to "steam roller" the delegates into acceptance of policies about which as individuals the majority may be dubious. A great business corporation, as long as it earns a dividend, never has to bother itself about its shareholders. It is the boast of the Roman Catholic church that it has not changed since its foundation; and innovators have always been driven either to schism or submission. Even in a comparatively new state like the Soviet Republic the proceed-

ings of the Communist party are full of accusations of this kind against officials.

In all large scale enterprise men who are desirous of avoiding great responsibility (and the majority of men is so desirous) are necessarily tempted to avoid great experiments. In a political democracy this obviously becomes an official habit where there is a tendency to a bureaucratic system. Nothing will be undertaken for the public for which it is not clamant. The difficulties of meeting the demands made will be exaggerated out of all proportion. Information necessary to the making of policy will be withheld, sometimes on the ground that it is not in the public interest to reveal it, sometimes by the argument that its collection would be unjustifiably expensive. Decisions will be made without the assignment of reasons for making them, or postponed until, in Bacon's phrase, the questions "resolve of themselves." The result is discretion, secrecy, conservatism, and all these minister to the preservation of power.

In modern times bureaucracies have, outside of Russia under the czarist regime, rarely been corrupt in a crude sense. Most of the advantages they obtain for themselves (security of tenure, superannuation, incremental salaries, annual vacation) are recognized as the necessary accompaniments of sound work. Nor has there been the tendency to nepotism which distinguished earlier types. Of course there have been scandals; in France notably there have been some sordid exposures worthy of the *ancien régime*. But it is in a broad sense just to say that in its political context the economic morality of the modern civil service, where it has had the advantage of permanence, has been far higher than that of private enterprise.

Its faults clearly arise from the difficulty of controlling experts in any department where action depends upon special knowledge which as a rule they alone possess and where mistakes of innovation may entail serious consequences. The size of the modern state in fact tends to make its government an oligarchy of specialists, whose routine is disturbed by the occasional irruption of the benevolent amateur. In England it may be said that the technical efficiency of the civil service has made it possible to avoid many of the larger evils of bureaucracy because the long period of service of outstanding statesmen gives to them a power of control not easily obtainable elsewhere. In Germany, on the other hand, at least until 1916, the statesman in office

tended to be the supreme bureaucrat who could avoid the consequence, to be faced in England, of having to meet a popular verdict. Moreover the English system of fairly constant and thorough inquiry into the whole condition of the civil service has made possible the introduction of a genuine flexibility of organization at comparatively frequent intervals. But it still remains true in England as elsewhere that the contact between the civil service, on the one hand, and the legislative assembly and the general public, on the other, is far too haphazard and incoherent. Here, it is probable, a great future lies before the advisory committee on which representatives of interests affected by the working of the departments shall have the opportunity of criticism and suggestion before the prestige of government is associated with the announcement of the result.

The characteristics of a civil service, which a French authority has described as permanence, hierarchy and profession, are probably fundamental to the proper performance of its work. The problem is to prevent the corporate degeneration of the civil service into a caste with a closed mind. There is no infallible method by which this can be accomplished. But it is possible, with experience, to indicate ways in which the degeneration can be minimized. (1) The political head of the department should be a person who has a permanent place in public life. He can then hope to acquire a sufficient knowledge of departmental operation to enable him to have a mind of his own. (2) The civil service should have direct and continuous contact with the representative public associations in order that public criticism of its work may be both well informed and coherent. (3) The retiring age of officials should be reasonably low. Otherwise the younger officials do not get the chance of really responsible work at a sufficiently early age, and the older become the prisoners of a routine. (4) There should be effective decentralization wherever possible. The more the official is brought into direct contact with the constituency he affects by his work, the more likely he is to be responsive to the need for innovation. Action and decisiveness require relation at the circumference; it is knowledge which demands centralization. (5) Efficient means should be organized for fairly frequent changes of work and for contact with foreign officials operating different systems. For an official in the diplomatic service, for example, to have direct experience of the

League of Nations is both refreshing and a valuable exposure to novelty. (6) In the early years of service egress therefrom should not, as in England, involve penalty. It is always bad for a bureaucracy to retain officials who do not find their true vocation in their work but shrink from the financial loss which is a consequence of forfeiture of pension rights. (7) Organic connection with the legislature is of high value. In this aspect the British municipal system creates a relation between elected and appointed members which is far more satisfactory than that attained in the parliamentary system. (8) In the conferring of administrative discretion upon civil servants there should always be safeguards of full publicity for its exercise. Where the discretion is of a judicial nature such a system of controls as that indicated by the Supreme Court of the United States in *McCall v. New York* (245 U. S. 345) is important. The experience, further, of France and Germany suggests the value of the right to sue the state in tort as against the validity of the Anglo-American system of virtual administrative irresponsibility.

BURGHLEY, LORD, WILLIAM CECIL (1520-98), English statesman. He came of a good Northamptonshire family and was educated at Cambridge and at Gray's Inn. He entered public service as Master of Requests during the reign of Edward VI and served that king subsequently as secretary and privy counselor. He participated actively in the establishment of Protestantism in England during Edward's reign, but found it prudent to accept Roman Catholicism when Mary reestablished the old faith in England. One of Elizabeth's first public acts was to create him principal secretary, an office which he held during the first thirteen years of her reign. In that capacity he was very largely responsible for the establishment of the Anglican church, for the direction of foreign policy and for the maintenance of internal order. He appears also to have been the queen's principal spokesman in the House of Commons. His great achievement during these critical years was to seat his mistress firmly upon her throne. In 1571 he was created Lord Burghley and in 1572 was appointed lord high treasurer. After that he was less concerned with the details of public administration, but he remained to the end of his life Elizabeth's most trusted adviser and had more to do than any one else except herself with the formulation of the royal policy both at home and abroad. He took a great interest in public finances, and though he did relatively little to improve the antiquated system of levying and collecting taxes he kept a close watch over royal expenditures and the conservation of royal resources. He did much

also to encourage English trade, to stimulate English ship building and to develop English industry. He revealed little interest in colonization, and although he would gladly have had England participate in the wealth of the new world he opposed the piratical methods of Hawkins and Drake as likely to precipitate war. His foreign policy was directed primarily to the maintenance of peace and the promotion of English economic interests. While he encouraged Protestant rebels in Holland and France he steadily, though not always openly, opposed the efforts of Leicester and Walsingham and Essex to draw England into open war on their behalf. Before his death he contrived to establish his son, Sir Robert Cecil, as the queen's chief adviser.

BURIAL CUSTOMS. See **DEATH CUSTOMS; FUNERALS.**

BURKE, EDMUND (1729-97), British statesman and political theorist. Burke was one of the most eminent of those political thinkers who have devoted their main energies to the actual conduct of affairs. He was born in Dublin and after a good but desultory education at Trinity College, Dublin, he crossed to England to study law but abandoned it for literature and politics. He first attracted attention by a work entitled *A Vindication of Natural Society* (1756), a brilliant satire on Bolingbroke's recently published works devoted to a vindication of natural religion, wherein he showed how the arguments by means of which Bolingbroke had reduced Christianity to deism would, if applied to politics, reduce ordered society to chaos. In 1759 he initiated the invaluable *Annual Register* of outstanding events, which he continued to edit, and in the main to write, until 1788. In the same year (1759) he became secretary to a prominent member of Parliament, W. G. Hamilton, who shortly afterwards (1761) was appointed to the staff of the lord lieutenant of Ireland. This appointment took Burke back to

his native city, and during his stay there (1761–64) he became convinced that the troublous condition of Ireland was due largely to the penal religious laws, to the commercial disabilities of the Irish, to the factiousness of its parliaments, to the corruption of its administration and to the absenteeism of its landlords. He never ceased throughout his public life to advocate reforms calculated to remove these evils.

A new and important stage in his career opened in 1765 when he was appointed private secretary to the Marquis of Rockingham, the official chief of the Whig party, who had just been summoned by George III to form a ministry. A seat in Parliament was also found for him before the close of the year. His political principles had already become fixed. He had acquired a profound admiration for the British constitution as determined by the revolution of 1688–89; he firmly believed in the government of the country by the landed aristocracy, of which class the Marquis of Rockingham was a splendid exemplar; he burned with a zeal for justice, a hatred of oppression, an enthusiasm for good administration, a devotion to religion. His immense intellectual power, the diligence with which he made himself master of every subject that he took up, the torrential eloquence wherewith he poured forth the wealth of his ideas, the insight that enabled him with unerring certainty to penetrate to the heart of every problem—these qualities soon gave him a unique position in the House of Commons and in the councils of his party. He speedily became, and for a quarter of a century (1765–90) remained, the formulator and interpreter of Whig policy to the world.

He had occasion to apply his principles to many practical problems of first importance. To begin with he had to defend the party or cabinet system of government against the system of administration by the monarch and the “King’s friends” which George III—modeling himself on Queen Elizabeth—was trying to reintroduce. This defense he made in his *Observations on the Present State of the Nation* (1769) and in his *Thoughts on the Causes of the Present Discontents* (1770) with a masterly thoroughness which makes those works classics in English political philosophy. The second great question that claimed his attention was the controversy respecting taxation and representation which had broken out early in George III’s reign between the American colonies and the mother country. Two speeches that he made

in Parliament on this matter (April, 1774, and March, 1775) together with his *Letter to the Sheriffs of Bristol on the Affairs of America* (1777) constitute in Lord Morley’s opinion the most admirable of all his utterances. Refusing to discuss the abstract rights of either the one side or the other he pleaded for a conciliatory policy in the interests of peace and prosperity. “The question with me,” he said, “is not whether you have a right to render your people miserable, but whether it is not your interest to make them happy.” His third great prepossession was the problem of the government of India, closely connected with which was the problem of the corruption of British politics by the overwealthy “ nabobs ” who returned from the East to buy up the pocket boroughs of the homeland. His prolonged attack on Warren Hastings may have been mistaken in detail, but it did much to impress all succeeding Indian administrators with a sense of their responsibilities.

The last great concern of his life was the French Revolution. His attitude of hostility to this epoch making event caused him to separate himself from many of his old associates and it finally led to the disruption of the Whig party. His famous *Reflections on the Revolution in France* (1790) was one of the most powerful and influential pamphlets ever written. He followed this up by other works in which he showed that precisely the same principles as had led him to oppose the policy of George III in England compelled him to condemn the revolutionaries in France. These principles were the organic nature of the state, the need of constant adaptation of institutions to circumstances, the peril of too sudden change and the imperative necessity of the recognition of the religious basis of society.

BURLAMACHI, PHILIP (died in 1644), merchant-banker and diplomatic agent. He was born in France of Italian stock. Entering into partnership with his wife's family, the Calandrini, he became the head of a banking association which spread a network of agencies over Europe. About 1605 he settled in England, where he soon achieved prominence as financier and merchant. Between 1614 and 1633 he was the chief financial agent of the English government. His connexions in northern Germany enabled him to act as paymaster and contractor for the various English expeditions which took part in the earlier stages of the 'Thirty Years' War. He paid and received for the home government large sums in the European capitals, was the paymaster of ambassadors and arranged for the pawning of the crown jewels in Amsterdam. After his naturalization in 1624 he became influential in Whitehall as the most active member of the select community of merchants which supplied the Exchequer with funds in anticipation of revenue. When phenomenal success as a lender led him to borrow money as a deposit banker he overreached himself and failed in 1633 with the crown as principal debtor. His bankruptcy produced a minor financial crisis in western Europe. Burlamachi was one of the first to devise a scheme for an English public bank. His plan, which never found its way into print, proposed an institution to furnish deposit facilities for traders and to provide means for "the payment of all considerable sums which are negotiated"; it was apparently to be supported by the credit of the city of London.

BURLAMAQUI, JEAN JACQUES (1694-1748), Swiss jurist, an adherent of the law of nature school and its greatest exponent outside Germany. His *Principes du droit naturel* (Geneva 1747) begins with a study of the nature of man considered as morally responsible and subject to law. Burlamaqui then attempts to establish the origin of rights in general. He discusses the norms of conduct, which he regards as derived from reason, the nature and origin of obligation, law as a system of reciprocal rights and duties, the nature of rules of law and the basis of sovereignty. He analyzes natural law and seeks to prove its existence, deducing it from the

divine order, moral instinct and reason. The *Principes du droit politique* (Geneva 1751) treats of the origin and nature of civil society, forms of government, the transitions of sovereignty and the reciprocal duties of sovereigns and subjects. Here Burlamaqui examines specifically the legislative, religious, punitive and economic rights of the sovereign. Although he favors absolute power and hereditary monarchy he regards a popular assembly as capable of changing the existing ruler. Finally, in dealing with international law, he discusses the foreign rights of the sovereign, the rights and necessities of war, public treaties and the privileges of ambassadors. Burlamaqui consistently maintained that international rights are nothing more than natural law.

ROBERT REIDSLOB

Works: The two books mentioned above were republished as one work, *Principes du droit naturel et politique*, 3 vols. (Geneva 1763), tr. by Nugent, 2 vols. (rev. ed. London 1763); they have also been translated into Spanish and Italian. The most notable editor and commentator of Burlamaqui has been Fortunato Bartolomeo de Felice, who published an enlarged edition, 8 vols. (Yverdon 1766-68), which was again revised by Dupin, 5 vols. (Paris 1820-21). *Consult:* Rivier, A., "Litterarhistorische Uebersicht der Systeme und Theorien des Völkerrechts seit Grotius" in Franz von Holtzendorff's *Handbuch des Völkerrechts* (Berlin 1885) vol. i, p. 433-35, and further authorities cited there.

BURLINGAME, ANSON (1820-70), American diplomat. Burlingame was born at New Berlin, New York, and later settled in Massachusetts. He was elected to Congress in 1855 and became known as an orator and as a leader of the anti-slavery forces in the House. After his defeat for reelection in 1860 he was appointed minister to Vienna, but his earlier advocacy of the Sardinian cause had offended the Austrian government and the appointment was changed to China. As minister to China, from October, 1861, until November, 1867, he made for himself a lasting place in the annals of American diplomacy. His generous disposition won the confidence of the imperial officials and also of his British, French and Russian colleagues. Largely because of Burlingame's influence with his fellow diplomats his six years in China saw an abatement of the aggressive tactics which previously had characterized the policies of the western powers. In November, 1867, Burlingame resigned his post and accepted appointment as head of a Chinese mission to America and Europe. Pleading for a policy of "fair play for China" he succeeded in

concluding at Washington in 1868 a supplementary treaty between China and the United States, recognizing the territorial integrity and sovereignty of China and the right of free immigration. With the large increase of Chinese immigration into California this last provision was later to become the cause of serious friction between the United States and China. In London Burlingame was able to counteract the influence of the "old China hands" and to effect a complete reversal of Britain's past policy in China. The mission was cordially received at Paris, Berlin and St. Petersburg and Burlingame succeeded in evoking more considerate treatment for the Chinese empire.

G. NYE STEIGER

Consult: Williams, F. W., *Anson Burlingame and the First Chinese Mission to Foreign Powers* (New York 1912).

BURNET, GILBERT (1643-1715), British historian and ecclesiastic. Burnet was born in Edinburgh, studied divinity and became professor of theology at the University of Glasgow. In 1674 he settled in London where as one of the most eloquent preachers of his generation and as a vigorous pamphleteer he consistently pursued a broad church policy. His lifelong advocacy of tolerance and his activities in behalf of Scotch Presbyterians and English Nonconformists may be traced not to a judicial temperament but to a belief that there were good men among the subscribers to all creeds. On the death of Charles II, since he had by his independence incurred the displeasure of James, he retired to Paris and later to The Hague. He won the confidence of William and Mary, translated and recast William's *Declaration* and crossing with him to England published an able defense of the revolution. He was rewarded in 1689 with the bishopric of Salisbury.

As a historian Burnet was something of a pioneer. For his *Memoires of the Lives and Actions of James and William, Dukes of Hamilton and Castleherald* (London 1677, new ed. Oxford 1852) he ransacked the available source material, printing many documents. He pursued the same course in his *History of the Reformation of the Church of England* (3 vols., London 1681-1715; new ed. by N. Pocock, 7 vols., Oxford 1865). Although full of inaccuracies and prejudices it was an endeavor not merely to narrate events but also to show underlying ideas and social forces, and in both method and aim provided a model for later writers. In the *History*

of His Own Time (ed. by Thomas Burnet, 2 vols., London 1724-34; new ed. by O. Airy, with supplementary volume ed. by H. C. Foxcroft, Oxford 1897-1901), Burnet's most important work, he hoped to supply a handbook for statesmen while justifying the ways of God to man. He succeeded in producing an inimitable account of the shifting political scene he knew so well.

LOUISE FARGO BROWN

Consult: Clarke, T. E. S., and Foxcroft, H. C., *A Life of Gilbert Burnet, Bishop of Salisbury* (Cambridge, Eng. 1907).

BURNETT, JOHN (1842-1914), British labor leader. Burnett first won prominence in 1871 as leader of the rank and file struggle for a nine-hour day in the Newcastle area. Although his election as secretary of the Amalgamated Society of Engineers in 1875 reflected a growing dissatisfaction with the staid craft union policy of the national unions, Burnett adopted in the main the traditional policy of his organization. An efficient negotiator, he was unable, however, in the prolonged trade depression of the decade, to do much more than maintain union membership and the nine-hour day. As a member of the Parliamentary Committee of the Trade Union Congress from 1876 to 1885 Burnett followed its policy in opposing independent political action by labor, and as its representative at the International Labour Congress in Paris, 1883, he supported a movement for non-political international craft organization. He was thus truly representative of the mid-Victorian phase of the British labor movement and out of harmony with the "new unionism" of the nineties.

In 1886, no doubt in recognition of his personal qualifications as one of the leaders who had contributed to the public acceptance of trade unionism, Burnett was appointed to the newly created post of Labour Correspondent to the Board of Trade. He held this office, which was later transferred to the Labour Department, until 1907. He was responsible for valuable reports on sweating (Great Britain, Board of Trade, *Report . . . on the Sweating System in Leeds*, Parliamentary Papers by Command, C-5513, London 1888, and *Report . . . at the East End of London*, Parliament, House of Commons, 331, London 1887) and on alien immigration into the United States (Great Britain, Board of Trade, *Alien Immigration*, Parliamentary Papers by Command, C-7113, London 1893). It was largely through his initiative that the government for the first time began the collection of

reliable information on trade unions and on strikes and lockouts.

H. L. BEALES

BURRITT, ELIHU (1810-79), American advocate of peace. His chief contributions to pacifist propaganda lay in his utilization of data from the social sciences and in his development of a technique of organization and publicity. Without abandoning the emphasis which his predecessors in the peace movement had given to moral and religious arguments against war, Burritt found new arguments in comparative philology, geography and economics. The evidence of related word forms and common roots corroborated for him the religious and humanitarian belief in the solidarity of mankind. Geographical studies convinced him that the unity of the globe and the interdependence of its parts made war an utterly irrational institution. He was among the first to see the importance of enlisting for the peace movement the support of free traders and laborers; as early as 1850 he urged workingmen "to unite and refuse to fight" ("The World Workingman's Strike against War" in his *Ten-Minute Talks*, Boston 1874). His *Year-Book of the Nations* (1855-56) was an able statistical analysis of the economy of the war system. In the field of jurisprudence he popularized the plan of William Ladd for a congress and court of nations, and labored successfully for the organization of representative jurists into a society for the codification of international law.

Burritt was the first pacifist to attempt on a large scale the organization of public opinion in the interest of peace. At critical points in international affairs he tried to propitiate mutual antagonisms by organizing in the countries concerned citizens' meetings for exchanging "Friendly Addresses"; during the Oregon crisis and the Anglo-French crises of 1848 and 1852 this "people's diplomacy" attracted wide attention. He was also the first who on a large scale utilized the press in furthering the cause of peace, inserting in almost forty daily newspapers of Europe incisive bits of peace propaganda. These "olive leaves"—blind advertisements—reached for several years perhaps a million readers each month. In 1848 he organized at Brussels the first international peace congress and was largely instrumental in the organization of those which followed in other European cities.

Burritt believed in the unity of all reforms designed to improve human relations and to re-

move misunderstandings and conflict between social groups. Therefore in 1853 he made a five thousand mile lecture tour in behalf of Ocean Penny Postage. He did something to realize his plan of "assisted migration" from Europe to America. From 1855 to 1861 he sought to avert civil war in the United States by devoting his energy, enthusiasm and slender resources to a campaign for compensated emancipation of the slaves.

MERLE E. CURTI

Consult: Elihu Burritt; a Memorial Volume, ed. by Charles Northend (New York 1879); Curti, Merle E., *The American Peace Crusade 1815-1860*, vol. I- (Durham, N. C. 1929-) especially ch. vii.

BURT, THOMAS (1837-1922), British labor leader. He came from a family of Methodist, Chartist, trade union traditions; at the age of ten he entered the mines and in adolescence began a process of systematic self-education, reading Wordsworth, Ruskin, much contemporary American popular philosophy, and finding in Adam Smith and J. S. Mill support for his belief in trade unionism. In the later sixties he turned a bankrupt organization into a miners' union comprehensive of the whole Northumberland coal field and recognized by the employers. He played an important part in the development of arbitration into a permanent machinery for pacific negotiation and in the adoption of sliding wage scales based on the selling price of coal. In 1874 he was elected to Parliament by Morpeth, a constituency swamped by newly enfranchised miners, and supported Gladstone, in whom he saw the champion of social, religious and legal equality. He held minor office, was made privy councillor and became "father" of the House of Commons.

After 1890 he was attacked with increasing bitterness by a younger generation of confessedly socialist beliefs, the ground chosen for their attack being his opposition to their demand for a state enforced minimum wage and state control of working hours and his persistence in an outworn faith in trade union bargain. His main work was the construction of a powerful but pacific union, the perfecting of machinery for industrial agreement and demonstration to a country of predominantly upper class leadership of the possibilities of democracy free from demagogic violence.

E. WELBOURNE

Consult: Burt, Thomas, An Autobiography, with supplementary chapters by Aaron Watson (London

1924); Welbourne, E., *The Miners' Unions of Northumberland and Durham* (Cambridge, Eng. 1923).

BURY, JOHN BAGNELL (1861-1927), English historian. From Foyle College, Londonderry, Bury entered Trinity College, Dublin (1878), and in 1880 spent six months at the University of Göttingen. In 1885 he obtained his fellowship at Trinity College. At the age of thirty-two he was elected professor of modern history and five years later regius professor of Greek in Trinity College, thus holding two chairs contemporaneously. In 1902 he was appointed regius professor of modern history in the University of Cambridge, a position which he held until his death.

Bury approached the study of history through his interest in classical philology, and the philological method left a clear mark upon his historical work. He made a permanent contribution, to our knowledge of the later Roman Empire and of the Byzantine period. In addition to many articles in the *English Historical Review*, the *Journal of Hellenic Studies*, the *Byzantinische Zeitschrift* and other scholarly publications he was the author of an important introduction to volume iv of the *Cambridge Medieval History* and of three masterly books, *A History of the Later Roman Empire from Arcadius to Irene*, 395 A.D.-800 A.D. (2 vols., London 1889), *A History of the Eastern Roman Empire from the Fall of Irene to the Accession of Basil I*, A.D. 802-867 (London 1912) and *History of the Later Roman Empire from the Death of Theodosius I to the Death of Justinian* (2 vols., London 1923).

A keen student of philosophy, especially that of Hegel, Bury was a convinced monist and rationalist; he attacked Christianity and other forms of theism as demanding of their followers a faith which reason could not justify. "There is nothing for it but to trust the light of our reason. Its candle power may be low, but it is the only light we have." Bury contributed frequently to the *Annual of the Rationalist Press Association*, and it was this philosophical interest which led him to write his *History of Freedom of Thought* (London 1913).

Yet Bury had his own faith, the belief in progress, which inspired his industrious life. This belief is founded on "an interpretation of history which regards men as slowly advancing in a definite and desirable direction, and infers that this progress will continue indefinitely." It thus implies that "a condition of general happiness will ultimately be enjoyed which will

justify the whole process of civilization" (*The Idea of Progress*, London 1920, p. 5). Further, the development must be conceived as necessary and certain; the theory would have little value or significance if future progress depended on chance or the unpredictable discretion of an external will. The historian's task is to contribute toward the ultimate synthesis of man's past which shall unify the process of the ages. History is not the dossier of an incompetent Providence, but the record of an uphill struggle in which the race of mankind, although heavily handicapped, has accomplished wonders.

NORMAN H. BAYNES

BUSCH, ERNST (1849-93), German writer on the theory of the cooperative movement. His three works, *Die Soziale Frage und Ihre Lösung* (Berlin 1890), *Der Irrtum von Karl Marx* (Basel 1894, 2nd ed. Stuttgart 1908) and *Ursprung und Wesen der wirtschaftlichen Krisis* (Leipzig 1892), all deal with the differences between the socialistic and the cooperative approach to the solution of the social question. Busch traced inequality of distribution to the process of exchange rather than to the system of production. He rejected the theory of class struggle and opposed the intervention of the state in economic affairs. He believed that through the cooperative organization of consumption it would be possible for the workers to effect a transformation of the modern capitalistic system. His doctrines provided the cooperative movement with a broader theoretical basis and exerted a considerable influence upon the German Social Democrats, whose attitude toward the cooperative movement had been indifferent or hostile. His influence extended to other countries, especially Switzerland and Austria.

Consult: Totomianz, V., *Konsumentenorganisation: Theorie, Geschichte und Praxis der Konsumgenossenschaften* (3rd ed. Berlin 1929) p. 19-25; Mühlberger, Arthur, introduction to the second edition of *Der Irrtum von Karl Marx*, p. 5-15.

BÜSCH, JOHANN GEORG (1728-1800), German economist. Trained primarily in the natural sciences Büsch served after 1767 as the director of the commercial school at Hamburg, now known as the Büsch Institute. He was active in every movement for social progress and left twenty-eight works on technological, historical,

legal and economic subjects. He was one of the leading precursors of German economic science.

As an economist Büsch was significant especially for his opposition to eighteenth century mercantilism and his advocacy of a more liberal economic policy. He favored a limited system of free trade and declared that an international division of labor would improve the material welfare of mankind more quickly than the most flourishing economic development under conditions of national isolation. Accordingly he opposed the artificial stimulation of domestic industries but supported an educational protective tariff, thus anticipating Friedrich List in this as at many other points. Büsch disliked chartered companies because they easily became monopolistic, and demanded the regulation of competition in international trade by a system of commercial treaties. Having coined the German term for carrying trade (*Zwischenhandel*) he was one of the first to appreciate the true importance of this branch of economic activity. In internal affairs he stood for unrestricted competition in trade, freedom of industrial occupation and modernization of the agrarian regime by gradual reform. He welcomed the machine as an agency for the promotion of mass consumption. Among other things he advocated the improvement of commercial law and the establishment of special commercial courts.

Büsch's economic system centered about his theory of monetary circulation. Regarding money as a medium of exchange and as a standard of value, he opposed the quantity theory. He believed that division of labor is produced by the circulation of money and attempted to refute the opposite view of Adam Smith. Similarly the velocity of circulation rather than the absolute quantity of money determined for Büsch the prosperity of a country. One of the earliest German writers on banking, he held that banknotes are merely certificates of deposit, although he realized that they need not be fully covered, and declared that the function of deposit and transfer banks (*Girobank*) is to simplify payments. He also broached the subject of a single international monetary unit. This interest in monetary circulation was reflected even in his writings on taxation, in which he upheld the taxation of current income rather than of property and showed that the money withdrawn in taxes is returned through the employment by the government of its subjects.

KURT ZIELENZIGER

Important works: *Abhandlung von dem Geldumlauf,*

2 vols. (Hamburg 1780, 2nd ed. 1800); *Sämtliche Schriften über Banken und Münzwesen* (Hamburg 1801); *Theoretisch-praktische Darstellung der Handlung in deren mannigfaltigen Geschäften*, 2 vols. (Hamburg 1792, 3rd ed. 1808); *Kleinere Schriften von der Handlung und anderem gemeinnützigen Inhalte* (Leipzig 1772); *Handlungsbibliothek*, together with C. D. Ebeling, 3 vols. (Hamburg 1785-97).

Consult: Nölting, J. H., *Joh. Georg Büsch* (Hamburg 1801); Roscher, Wilhelm, *Geschichte der Nationalökonomik in Deutschland* (Munich 1874) p. 559-76; Sieveking, Heinrich, "J. G. Büsch und seine Abhandlung von dem Geldumlauf" in *Schmollers Jahrbuch*, vol. xxviii (1904) 77-115, 559-98; Biensfeldt, J., *Johann Georg Büsch* (Erlangen 1910).

BÜSCHING, ANTON FRIEDRICH (1724-93), German writer on economics, statistics and geography. He was the founder of comparative political statistics. His *Vorberichtung zur gründlichen und nützlichen Kenntniss der geographischen Beschaffenheit und Staatsverfassung der europäischen Reiche und Republiken* (Vienna 1758; 6th ed. by G. P. H. Loumann, Vienna 1802) was the first work to abandon the method of treating countries individually and to make a comparative study of the population, territory, government and particularly of the economic aspects of national life. His monumental work is the *Neue Erdbeschreibung* (13 vols., Hamburg 1754-1807; tr. in part by P. Murdoch as *A New System of Geography*, 6 vols., London 1762), ten volumes of which he completed before his death. It contains statistical and other information on the resources, industry, political systems and general culture of all the countries described; it initiated the politico-statistical method in geography. Büsching also founded and published twenty-three volumes of the *Magazin für die neue Historie und Geographie* (1767-93). The first periodical to deal with politico-statistical material, it furnished valuable statistical data on the political conditions of various states.

HELLMUTH WOLFF

BUSINESS is a term which etymologically means the state of being busy and hence tends to become identified in meaning with whatever there is to be busy about. This accommodating quality makes it impossible to compile a reasonably compact group of generalizations to cover the manifold senses in which the term is used

in the literature of the social sciences. Even in the relatively restricted field of economics it is frequently employed in a comprehensive sense to designate any activity directed toward gaining a livelihood.

While its use is extremely catholic the term business is nevertheless commonly associated with a system by which the process of profit making organizes and directs economic activity. Sometimes it is employed to indicate the immediate aim of profit seekers, as when the expression, "this is a business transaction," differentiates the dealing from one involving motives other than the acquisition of profit. It is also used extensively to designate methods currently employed in the process of profit making, such as financing, purchasing and selling, regardless of whether or not they are specifically directed to profit making. Religious societies, cooperative associations, departments of government and members of professions dedicated to purposes other than the realization of profit are customarily described as being engaged in business in so far as they use methods associated with the process of profit making.

The peculiar nature of business can be readily understood by contrasting it with other systems by which economic activity might be organized and directed. In any community there is a great array of physical, mental and mechanical processes by which human and material resources are converted into commodities and services for human use. The carrying on of these processes is economic activity. This activity might be under the supervision of a military dictatorship directing every phase according to calculations of what would constitute the most effective military establishment. In war time economic activity is generally brought in some degree under such a type of control. There might be dictatorship by a religious organization exercising a similar supervision according to standards believed to promote righteousness. There were traces of such a type of control during the Middle Ages. On the other hand economic activity might be organized and directed by government officials with the object of apportioning its burdens and benefits equally among the members of the participating group. This is one of the plans with which the term socialism is associated. In contrast to these methods business is a system whereby economic activity is controlled by those seeking a profit or surplus above the cost of making goods and services available for human use. In such a system there

is not necessarily a central agency for planning and coordination, since its only essential is the possibility of profit making and its potential scope that range of economic activity adapted to such a purpose.

The prerequisites of business are: the existence of some standard, however crude, upon which to base calculations of profit possibilities; enough security through recourse to physical force or law to permit a course of action based upon such calculations; and an accumulation of products beyond immediate consumption requirements. So long as people are dependent for their livelihood upon the direct consumption of all they produce, business cannot exist because there is no place for profit making. Thus business is dependent upon something akin to capitalism in its requirement of an accumulated store of products, but its emphasis is upon the use of these products for profit making rather than for further production.

It does not follow of course that if these prerequisites have been fulfilled a business system will automatically spring into being. Nor does it follow that the general use of devices commonly associated with business involves commitment to a business system. It is essential to the existence of such a system not only that there be fulfillment of the prerequisites enumerated but also that these resources be directed to the end of profit making, a process which necessarily involves the use of business devices. It is in the combination of these three, to which direction is given by the desire to make profits, that a business system emerges.

Originated at some time prior to that disclosed by written records, business was already highly developed in what we are accustomed to call the ancient world. An extensive maritime and merchandising trade was controlled by a profit making system which in the Roman Empire had come to include both banking, as a money changing process, and elaborate machinery for speculation and investment. With the collapse of the Roman Empire this business system was virtually wiped out in northern and western Europe, but in the area controlled by Constantinople a substantial trade tapping the Orient and the western Mediterranean continued to be organized and directed by profit seekers. After the crusades the center of the business system gradually shifted to the Italian cities and later to Holland, where through steady advance in profit making machinery its modern expansion began.

The story of this expansion in all of its ramifications is little less than the story of the rise of modern western civilization. Christian churchmen contributing to whole souled pursuit of profit by reconciling personal gain with piety; explorers finding new lands and armies clearing the way for traders; kings fighting with princes and popes to establish national states and then with parliaments to hold their power; philosophers inventing or rediscovering theories of "natural rights" and "individualism"; scientists experimenting with microscopes, steam and electricity; lawyers perfecting devices for controlling property; all have important places in the story of the development of modern business—a story so vast and complex that it has never been put together in a complete and moving whole.

In paving the way for the modern business system three developments each with its own extensive history seem to have been of peculiar significance. The first was a commercial revolution which, gaining momentum during the fifteenth and sixteenth centuries largely as a result of the discovery of the Americas, expanded commerce from what was primarily traffic in luxuries to that in homely products for consumption by masses of people and created a large group of prosperous traders skilled in the ways of profit making. The second development was the industrial revolution, hastened by the pressure which the earlier commercial expansion had placed upon methods of production, precipitated by a series of mechanical inventions in England in the eighteenth century and still continuing its course with no evidence of waning vigor. The third was the elevation of the doctrine of *laissez faire*—that competition can be trusted to guide economic activity to socially desirable ends—to the position of a dominant social policy during the eighteenth and nineteenth centuries. The commercial revolution built the framework for a national and international business system but one that was definitely limited by the manageability of crude industrial processes. The industrial revolution removed this limiting factor; and widespread faith in the doctrine of *laissez faire* at least as a domestic governmental policy resulted in sanctions favorable to business expansion.

Before the mechanical inventions of the eighteenth century formally ushered in modern industrialism, many of the devices associated with modern business control of economic activity were known. A wage system had been

used by profit making enterprises in the Roman Empire; accounting was quite highly developed by the Italians in the fifteenth century; insurance was being extensively used by Dutch business enterprises in the sixteenth century. The operation of a type of reserve banking system by London goldsmiths in the middle of the seventeenth century was followed by the establishment of the Bank of England in 1694; and prior to the middle of the eighteenth century stock speculation—much of it in various kinds of "bubbles"—was being extensively practised. The coming of industrialism, however, not only opened vast new avenues for profit making but also made possible a great extension of business control and its concentration on a much larger scale in individual enterprises. It is not so much the devices generally associated with modern business control of economic activity—wage systems, corporate investment, credit, etc.—that give it its distinctive character but rather the scope, power and pervasiveness of the system made possible by modern industrialism with its machine technique.

In the ancient world and throughout the Middle Ages in Europe business was confined largely to what would now be classified as finance and commerce as opposed to industry. Agriculture and the fabricating of goods were organized for the most part along lines other than those directed primarily toward profit making. With the expansion of trade during the commercial revolution there was a steady extension of business control to industry, notably in the field of textile production; but it remained for sweeping changes in industrial technique, particularly concentrated in England toward the end of the eighteenth century, to remove important physical barriers to any general invasion of industry by business.

The extension of the business system, however, was gradual and in extent has varied widely from country to country and in the various branches of economic life within countries. In England conditions during the latter part of the eighteenth century were singularly propitious for its rapid spread. The previous expansion of trade had placed funds at the disposal of people alert to profit making possibilities. Enclosures of agricultural lands for sheep raising had driven large numbers of people off the soil and created a floating population desperately in need of a chance to make a livelihood. Many of the raw materials essential

to industrialism were at hand. The view that the rich and poor alike should for the general good be required to look out for themselves in the struggle to make a living was in its ascendancy among those in power. Consequently when ways were discovered to apply power to tools, concentrate workers in factories and speed up transportation to steadily growing markets the path was already largely cleared for a rapid expansion of the business system. On the continent of Europe and in the United States the spread of business control to industry was much slower than in England. On the continent the Napoleonic and revolutionary wars put a blight on economic development over large areas, and social, economic and legal arrangements peculiar to various countries also held back the expansion of business control. In Germany, for example, a survival of certain important phases of the guild system of production as well as a demoralizing lack of political unity contributed to retard the development of large scale industrialism under business control long after it was extensively under way in England. In France among many factors contributing to a slower expansion of the business system was the continuing opportunity for workers to be relatively secure in tilling the soil, one of the activities less adapted to business control. In the United States the development of business was retarded relatively to England by the existence of a great frontier upon which successive waves of settlers advanced to carry on a system of production designed in substantial measure for direct use rather than for profit. The business system had however been expanding almost from the day the first European settlers arrived, favored not only by social and legal arrangements but by an abundance of resources for profit making. The passing of the frontier by closing the most general alternative to direct participation in a business system made it possible for that steadily expanding system to gain undisputed control over the economic life of the nation.

It is only in a general sense that the economic life of any community can be said to be controlled by business. Much of the economic activity in the United States, such as that of the government, of the churches or of housewives, is not motivated by the desire for profit, while in Russia, a country formally committed to a type of socialism, a large share of economic activity is controlled by the process of profit making. Thus in referring to the economic life

of a community as controlled by business one means only that the profit and loss calculus of that system is dominant and that even those who do not participate directly in the effort to make profit must pay heed to it. This is peculiarly true of the United States where business, much more retarded in its initial development than in England, has not only come to dominate the economic life of the nation but has reached over national borders to confound other nations with its strength, vigor and firm devotion to its major objective, profit.

In spite of the extensive development of business in the United States it is still possible to study currently its most primitive stages in the production and barter of natural products for profit; and individually owned profit making establishments operating on a very small scale are still abundant. With the advance of industrialism, however, business has been increasingly taken over by corporations engaged in producing highly specialized goods and services for national and international markets. Manufacturing corporations gather equipment and material from all parts of the world through enterprises specializing in mining, agriculture and transportation; they convert this material into standardized products, sometimes relying on the coordinated activity of hundreds of thousands of factory workers; and they dispose of these products through business organizations engaged in advertising, wholesale and retail trade, each with its specialized body of workers. Such operations are typically financed through investment and commercial banking enterprises linked in national and international systems of their kind, and may depend for their ultimate success on purchases by hundreds of thousands or even millions of consumers. In such a sequence of operations a serious upset at any point is reflected with varying degrees of intensity throughout the whole system of enterprises. The failure of an enterprise supplying raw material or a breakdown in transportation may result almost immediately in unemployment of factory workers and in a consequent falling off in consuming power reacting through a connected chain of enterprises engaged in wholesale and retail trade and affecting the welfare of countless persons in no way responsible for the initial disturbance. This delicate adjustment of highly specialized enterprises, dependent for their individual success not only upon the coordination of vast and complicated processes but also upon the effective cooperation

of a great chain of interdependent enterprises and shaping the welfare of armies of workers, consumers and investors by their performance, is an outstanding characteristic of the modern business system and differentiates it markedly from business prior to the coming of modern industrialism.

In accounting for the fact that profit making is allowed to control such a delicately adjusted economic structure requiring a high degree of cooperation for successful performance, reference is generally made to the sanctions and restraints of a "system of free private enterprise" of which profit making is a part. This system, in one sense a working model of the doctrine of *laissez faire*, has as its key elements the institutions of private property, contract, profit making and competition. The institution of private property roughly speaking fixes the ownership of the resources coming within its scope and the rights attached to that ownership. By contract or agreement freely entered into by two or more parties to their mutual satisfaction machinery is provided for bringing property and those who are to use it into a dependable relationship. It is largely through contract in the broad sense of the term that property in all its countless forms is entrusted to the process of converting human and material resources into products and services for human consumption, that labor is obtained and that these products and services are ultimately disposed of.

The opportunity to make profit is depended upon to induce those having control of human and material resources through ownership of property or through contract to put the resources to work producing goods and services. And competition is the force primarily relied upon to hold profits within reasonable limits, to protect all those involved in the system from exploitation, to prevent any of them from making unreasonable exactions for their property or labor and to knit the process by which people gain a livelihood into a smoothly and steadily working whole.

Viewed as part of a system of free private enterprise, business is a set of arrangements providing those participating in it with rewards proportionate to their contributions to the production of goods and services and making these goods and services available for consumption on the best possible terms. But from the point of view of those engaged in business as profit seekers, generally called "business men," the

acquisition of profit is an end in itself, if for no other reason than that failure to acquire it threatens their elimination from the ranks of the profit seekers. The difference between the conception of business as a device for providing human beings with the means of livelihood and as a way of acquiring profit represents the essential difference between economics and what is commonly described in the United States as the science of business. Thus profit, the main-spring of business, is treated by economists as a payment for performing some function, positive or negative, in the process of providing goods and service. Profit from the viewpoint of the science of business, however, is the difference between the receipts and expenditures of a profit making enterprise, to be treated as an end in itself.

To the extent that business dominates economic activity it is economical to have it carried on with a minimum waste of human and material resources, and if a balanced competitive situation exists this way may also be the most profitable. It is largely on the assumption that success in profit making and economical utilization of human and material resources go hand in hand that public funds have been extensively appropriated in the United States for studying and teaching ways of profit making. The assumption may or may not be true in the case of any particular effort to make profit. There is no certain and necessary relationship between "sound business" - that which gives profit seekers a satisfactory margin between expenses and receipts - and socially economical management.

While those directing profit making enterprises are given an initial control over business, in so far as it is a part of a larger system of free private enterprise the extent of this control is dependent upon the bargaining ability of all the various participants. Thus if laborers are in a strong bargaining position they can presumably obtain a relatively large share in the control exercised over business and a relatively large share of the income gained by profit seeking enterprises in which they participate. Likewise consumers have a potential control over business through their power to discriminate in purchasing. It has not however been the history of business under a system of free private enterprise that control over it has been seriously compromised by wage workers or consumers. Those directing profit making enterprises have as a group maintained firm control over the system and have been consistently successful

in using this control to obtain relatively large incomes.

This success has been reflected in the general conception of what constitutes being "in business" or having a business career. All those who spend their working lives in a business system whether as common laborers or as executives of great corporations have business careers. Those who earn their living by working for wages paid by profit making enterprises are no less committed to business than are those who direct their labors. However, because the control of the business system is lodged with those directing profit making enterprises, it has become customary to associate a career in business with the acquisition of profit or what might be termed the profit controlling side of the system.

With the increasing direction of business by employees of large corporations the difficulty of formulating any concise conception of an individual business career has been enhanced. Before the widespread application of the corporate device such a career was envisaged as one in which the owner of property whether in the form of money, materials or equipment put it to use for profit making under personal direction and personally pocketed the gains or bore the losses. Such an individual was the type of entrepreneur of eighteenth and early nineteenth century economic literature. While small retail shops, many farms and some substantial industrial enterprises are still conducted on such a basis, the dominant type of business organization at present is the corporation to which owners commit their property by contracts of limited liability to be used by hired workers ranging from unskilled manual laborers to highly trained specialists. Under such circumstances the difficulty of specifically identifying any group as peculiarly occupied with business careers is obvious. The process of profit making is clear, but the point at which an employee moves across the line that separates the "hired help" from those having business careers is difficult to locate. That there is such a line determined roughly by the degree of individual indispensability to a profit making enterprise is none the less true.

Because of their key position in a system which constrains all participants to pursue a course directed toward personal gain and because of their success in following such a course, those in the United States who control large profit making enterprises enjoy what is probably a greater prestige than that of any other group.

In older countries where there are continuing systems of aristocracy based upon birth or royal favor success in business is somewhat less of an end in itself.

The marked material success of those in control of business in the United States is responsible in part for the widespread adoption of business devices and methods by enterprises not designed to make profit. Advertising has come to be used by religious establishments for what is not infrequently described as "selling the Lord's message"; departments of government and school systems make wide use of business methods in such operations as purchasing supplies and equipment, directing the work of employees and accounting for funds. It is true that since profit making dominates economic activity in the United States non-profit making establishments in dealing with enterprises conducted for private gain are sometimes forced to adopt such methods for self-protection. However, the stronger factor in the situation is the conviction that such methods are efficient. It is this idea of efficiency that generally underlies the much voiced demand for

which usually means that the government in expending funds on operations designed to promote the public welfare should more generally use the criteria and methods associated with profit seeking.

The prestige and power of successful business men in the United States also contributes to a movement of uncertain proportions and meaning to "make business a profession." An important contributing factor is the growing recognition that competition is neither a certain nor a consistently satisfactory regulator of the business system. This realization led to a formidable trade association movement in which competition is tempered by cooperation; it gave force to the contention by some business leaders that there must be a compensating control in the form of a professional attitude to obviate the necessity of more formal control by the state. What is generally meant by such a professional attitude is recognition that profit making is not an end in itself but a way of providing people with a livelihood and that profit seekers should formally accept a social responsibility in directing the process. Some conceptions of business as a profession include no more than a vision of a body of specialists trained in the ways of profit seeking, having group standards of performance and enjoying public recognition

in this capacity; but the predominant idea seems to be that of making the widely circulated business motto, "he profits most who serves best," dependent upon a professional code of binding force rather than upon a variable factor of individual good will and the exigencies of competition.

As business has increased in scope and power, governments have supplemented the earlier policy of fostering and protecting it by the adoption of a great variety of measures designed to direct it to social ends. In the United States most of such measures have fallen into three main groups: first, those designed to establish a plane of competition believed to be socially desirable; second, those intended to remove obstructions to competition within the limits set; and finally, measures to regulate the conduct of business enterprises believed not to be adapted to socially satisfactory control by competition. In addition an important control has been exercised over business through taxation. In some cases, such as the levying of a prohibitive federal tax on the note issues of state banks to drive them out of circulation, taxation has been applied explicitly as a regulatory device. Explicit use of the taxing power for the regulation of business, however, is now regarded as offensive to the federal constitution, and the effect of taxation on business is, in theory if not always in fact, incidental to its other purposes.

Attempts to establish a socially desirable plane of competition by governmental action have been based on the general theory as phrased by Henry C. Adams that "the law is an agency for the realization of the higher ideals of men by guarding them from that competition which would otherwise force them to a lower plane of action, or out of business." In the modern business system with its great discrepancies in economic power, its impersonal and long distance relationships and its control over highly complex products, the ways of competitive retribution may be slow and uncertain. By exploiting workers in a weak bargaining position or selling deleterious products a profit making enterprise may not only prosper at least for a time but may also force its competitors perhaps most unwillingly to follow suit if they are to survive. To check competition as a destructive force many laws designed to establish what legislatures have believed to be a desirable plane of competition have been enacted. The various branches of the government of the United

States have also occupied themselves extensively with efforts to make competition effective on the plane set. In order to give this force a chance to work, Congress and the state legislatures have passed a large volume of "anti-trust" legislation designed to remove obstructions to competition in such forms as monopoly, conspiracy and agreements in restraint of trade.

In addition to trying to check competition believed to be undesirable and removing obstructions to "wholesome" competition the various governments of the world have also established regulatory machinery to control particular enterprises where monopoly is essential to satisfactory service or where competition has failed to produce results satisfactory to legislative bodies. Such regulation generally carried out in the United States by administrative commissions with provision for review of their decisions by courts varies widely in the case of different enterprises and from jurisdiction to jurisdiction. It is concerned primarily with the prices charged for standardized commodities and services. The government also regulates some enterprises by competing with them as a proprietor. Government competition, for example, serves to regulate certain privately owned and operated electric power and light companies. However, the instances where branches of government are engaged as proprietors of enterprises capable of yielding a profit are relatively few. "Less government in business," the companion piece for "more business in government" and generally meaning that the government should not occupy any profitable fields of endeavor, is still usually backed by an effective political force.

BUSINESS ADMINISTRATION may be defined as the science and art of conducting an enterprise with a maximum of efficiency and a minimum of cost. The administration of a project not only considers ways and means but weighs values and determines ends to be sought. There is a growing recognition of the separate roles of administration, management and organization. Administration, whether or not it is distinct in personal composition, is distinct in function from the management. Its function is to determine corporate policy, to coordinate finance, production and distribution, to point out the general path which is to be followed. Management is charged with the execution of policy within the limits set by administration; it devises methods and improves processes. Organization is the tool by which management achieves the ends aimed at by administration. Determination of the formulae which the engineer is to apply is the function of scientific management. But it is administration which in the first place, within the limits of the socio-economic environment, determines the situation for which formulae must be found.

It is only in comparatively recent times that business administration has been set apart as a distinct function in economic life. Even the vast business development following the industrial revolution failed to liberate business from the trial and error methods, the exclusive dependence upon native shrewdness and energy, that had characterized business since time immemorial. In England the period of *laissez faire* afforded dazzling opportunities to the acquisi-

tive captains of industry who cornered the market or secured special concessions but had little interest in scientific administration or management. During the corresponding period in the United States the chief activities were farming, shopkeeping, small manufacturing and some foreign trading. Individualistic effort prevailed. Trading was on a shrewd, narrow basis and the chief virtues were the ability to keep out of debt and to work hard. Later the scale of operations broadened. Nevertheless, during the nineteenth century natural resources such as fertile farming country, dense forests, rich deposits of minerals, were acquired, appropriated and exploited under a system of opportunistic individualism.

By the end of the century this race for appropriating natural wealth had been run. In some fields intense competition among the various entrepreneurs was forcing attention to the methods and costs of production. In others large scale organizations had achieved virtual monopoly and had settled into the routine administration of their properties. Business then turned to the intensive cultivation of markets for the sale of its products. An economic consequence was mass production of goods for consumption by wage earners generally, and such production had to be based on low costs. These low costs could be attained in many cases only by the most rigorous study of methods, materials and organization and a scientific approach to problems of management and administration.

In both the competitive and the monopolistic industries the importance of improvements in administration was recognized. In the competitive industries progressively improved methods of production and distribution became almost compulsory because of price competition. Large scale industry magnified the importance of every detailed improvement, since a slight decrease in waste or the utilization of some small by-product might mean enormous savings. The consolidation of ownership of industrial plants into holding companies has likewise been an important influence, since financial powers were given an opportunity to compare costs in the various units under their jurisdiction. The competition created within their own organizations has often been more scientific and intelligent than the blind search for reduction of costs which has gone on among independent concerns. The spread and growing complexity of the corporate form of business organization resulted in the development of a management

group whose interests and actions became increasingly independent of ownership. It contrasted sharply with the older type of small scale owner-manager. This change gave a considerable stimulus to a detached and scientific approach toward problems of administration.

Other developments affecting the type of administrators called for in industry were the political and economic changes which took away from the employer legal and economic sanctions for the control of labor. Some employers came to understand that greater productivity could be secured from workers by winning their co-operation than by relentless driving. In America labor has always been relatively scarce, especially in recent years. As a result of the restriction of immigration employers have been forced to look elsewhere than to cheap labor for means of economical production. One of the most important consequences has been the increasing application of research to the relationship of management and men.

The advances made in the social sciences have been an additional stimulus toward new viewpoints. The newer psychology in particular, with its analysis of personality maladjustment and integration, has opened the door to intelligent control of factors vital to the morale of the workers. The rapid strides made in statistical economics and cost accounting in the past twenty years have made possible manipulation of quantitative data to bring out significant relationships formerly buried in general reports.

The result of all these economic and social developments has been a tendency toward the rise of a profession of business. There is a growing reliance on research and science, an increasing willingness to prepare oneself for a business career through training, a greater appreciation of standards of performance and encouraging signs of recognition of the ethical and social obligations of industry. Executives with technical knowledge have been relieved of the purely financial manipulations expected of financiers and owners and have therefore been free to inject a professional attitude into the conduct of the enterprises under their jurisdiction. Everywhere in America the special talents necessary to administer a business and the technical character of such ability have thus become recognized. One evidence of this has been the change in the type of executive called upon to direct important enterprises. The virile individual who displays his ability chiefly in resourceful action during emergencies has been

gradually replaced by the quiet planning type who looks so far ahead that he does not allow emergencies to arise.

The work during the early years of the twentieth century of Frederick W. Taylor, the father of modern scientific management, has caused him to be widely regarded as the founder of business administration. His investigations were devoted, however, entirely to technique of manufacturing operations. The only relation of Taylorism to business administration is that each is an application of scientific method, but administration applies the method to the whole range of industrial problems—from launching an enterprise and plant location to administrative organization and marketing.

The growth of interest in business administration has been rapid. Schools of business have been established in the leading colleges and universities of America. By 1915 there was a large and growing body of literature, most of it devoted to techniques, but some of it evidencing evaluations of principles and objectives. Although there was considerable interest in the principles of business administration in Europe prior to the World War it has become enormous since then and American methods are the subject of admiration and study. In part this is due to envy of the prosperity which American business has enjoyed and to the difficulty experienced by European firms in competition with American concerns. In particular the experience of the Ford Motor Company and other American automobile companies has captured popular imagination. Students visiting the United States have observed that, as compared with the affection exhibited in continental countries for old machines and old plants, American concerns are continually scrapping equipment, discarding methods and looking for new models. Throughout Europe there has thus arisen a dissatisfaction with the traditional and antiquated methods, an eager search for improved practices and an unflagging effort to adapt industry to the new conditions. Everywhere there is an interest in rationalization, a term which according to the Reichskuratorium für Wirtschaftlichkeit, the central official body charged with the study of rationalized methods in Germany, may be defined as follows: "Rationalization consists in understanding and applying every means of improving the general economic situation through technical and systematic organization. Its object is an increase in the standard of living by the provision of better and cheaper goods in larger

quantities." It proposes application of the scientific intellectual method not only to the problems of industrial management within the framework of existing industry but to the reconstruction of economic life in the large. This movement is observable in England, Germany, France, Czechoslovakia and Poland and particularly in Russia, where scientific management is regarded as the essential basis of industrial progress.

The United States is properly known as the home of scientific management. Germany more recently has taken up the movement with great vigor and shows remarkable progress. For ingenious internal organization of the plant the American is justly famed, but it is the German who has most successfully managed the affairs of whole industries as units. Although handicapped by a large population and comparatively limited resources Germany has been enabled by superior physical technology and business administration to occupy an imposing place among modern nations.

In Russia the science of business administration has for the first time been applied by a government and on a national scale. In their frantic efforts to industrialize a large agricultural country the Russians have drawn upon America and western Europe not only for machines and technical processes but for knowledge of methods of coordination. The elimination of profits as the aim of economic activity has, however, necessitated a revision and additional development of the borrowed technique.

In general practise the business administrator deals with the business unit while the management deals with the production unit. The business unit is defined in terms of financial control, the production unit in terms of technological processes. Of course there is necessary overlapping and in the last analysis, although details of execution are problems of management, long time planning and organization of industry are concerns of administration.

Preminent among the activities of administration are financial operations. The administrator, when the enterprise is launched, must determine the relative merits and possibilities of securing capital by subscription to stock, by issuing short or long term bonds or by other forms of indebtedness. He must determine the desired ratio of fixed to working capital and must maintain access to additional capital from such sources as commercial banks and the open market. He must forecast intelligently expenses

and watch closely actual current expenses. To this end administrators are utilizing scientific budgeting and improved methods of cost accounting. In the matter of business organization there is a decided trend toward functional classifications. Business departments are being created on the basis of the function they serve, such as planning, material control, purchasing, sales promotion, accounting, personnel. A new tendency is that of having executive decisions made by committees rather than by line officials. This procedure coordinates responsibility and pools the fruits of experience but may result in loss of flexibility. Indeed one of the most difficult problems is to secure centralized leadership and at the same time flexibility and decentralized responsibility. Attempts to attain coordination and accuracy have resulted in elaborate systems of reporting and checking.

Control of production at a regular pace, utilizing all departments efficiently and having goods ready for shipment at desired dates, is aided by statistical devices such as the progress chart. Independence of seasonal and other fluctuations has been attained in some industries by developing side lines of by-products, by securing advance orders and by vertical integration to maintain steady sources of raw material, transportation or sales.

In the field of marketing there has been great improvement in statistical and psychological method. Analyses of market areas and establishment of territorial quotas have revealed new sales possibilities. Utilization of general forecasts of business and trade conditions has facilitated adjustment to market conditions. Establishment of reliable channels of retail distribution has increased volume and regularity of sales. Education of salesmen in the uses of a product rather than in the so-called art of salesmanship has put sales upon a sounder basis. The fine art of creating new wants and breaking down sales resistance through modern advertising, which apparently had infinite possibilities, has recently been subjected to close scrutiny and advertising budgets are being more carefully regulated.

Psychological treatment of personnel problems has advanced. Careful analyses of working conditions, mental as well as physical, and the providing of opportunities for self-expression and recommendations by workers are increasingly employed to forestall the growth of labor difficulties. The growing importance of scientific business administration is evidenced by the organization of various professional societies

The Taylor Society is an organization with international membership for the promotion of better management. Originally launched to promote the principles of scientific management as developed by Frederick W. Taylor it has during the past decade broadened its scope to include a scientific approach to all phases of administration, such as production, marketing, finance and industrial relations. It holds meetings and conferences from time to time, publishes a bulletin and sponsors authoritative volumes on management.

The largest and most active of the associations interested in the art of business administration is the American Management Association, which includes companies and individuals organized to exchange experience and to study management methods. Because it is a reorganization of an earlier group which had limited its interest to matters of labor the present association may be said to date from about the post-war depression of 1921. Its educational influence is exercised through numerous discussion meetings and conferences held in various parts of the country and in the wide distribution of the proceedings, which are conveniently published in leaflets on special subjects and constitute an indispensable library of American management practise.

There are several other associations of this character such as the Management Section of the American Society of Mechanical Engineers, the Society of Industrial Engineers, the National Association of Cost Accountants and more localized groups. The United States Department of Commerce, through various sections, particularly the Division of Simplified Practise, has arranged numerous conferences of business men which have had educational influence in promoting better administration. Its various publications sent out widely to industrial concerns have brought to general attention much significant knowledge.

In 1927 the International Management Institute, a world wide association for promoting business administration, was organized at Geneva. Its aims include the securing of the maximum efficiency of labor with the minimum of effort, the promotion of standardization, the avoidance of waste, the improvement of methods of distribution and of transportation and the general application of enlightened methods to economic organization.

Business administration, in spite of the spread of special educational institutions and profes-

sional associations, can hardly be said to have become a definitely organized science. There is of course a considerable body of tested procedure with respect to business methods which comes more properly under the heading of scientific management. Agreement upon general policies and administrative decisions, however, is still far from being attained. Indeed, although knowledge of processes necessary for business conduct may be reduced to a science, the administration of that knowledge, dependent as it is upon relative values and upon personality, will always remain an art. The student of the most advanced principles of administration is dependent upon the aid of such technicians as engineers, accountants and lawyers and upon people of practical business experience who can supply the exact knowledge upon which business administration is predicted. Although many practical business men are frankly skeptical about the merits of the professional administrator occasionally called in as consultant or advisor there is a tendency to resort to private experts in acute situations. Likewise in times of business reorganization it is sometimes found expedient to retain administrative consultants, who render service for a fee. Although highly specialized and coordinated systems of administration have to some extent resulted in loss of flexibility in the lower levels of management they have also led to a breaking down of traditional viewpoints and a willingness to face new problems intelligently.

From the broad social standpoint implications of business administration are far reaching. As with any other instrumentality its significance depends on the purpose for which it is used. It undoubtedly strengthens the position of the persons directing capital (not necessarily the investors) but it also opens new vistas for public regulation of business. In so far as ends of industrial processes are subject to scrutiny the profit motive tends to lose respectability, and enlightened leaders tend to accept the social responsibilities which underlie economic activities.

BUSINESS AGENT' is the title usually given to the general executive officer, formerly called the "walking delegate," who represents a local union or council in its daily business and whose work consists for the most part in enforcing union standards and verbal or written agreements with the employer. In this connection he is expected to recruit new workers on the job and to pass on to members information about available employment opportunities. The enforcement of union standards involves as secondary functions superintendence of the apprentice system, collection of fines and back dues, guarding of the trade jurisdiction and directing the work of the shop stewards. The business agent usually has few secretarial duties. Other duties, devolving upon him by reason of his superior information and powers of leadership, include representation of the local on central labor bodies and trades councils and at national conventions, watching legislation and lobbying for the trade. In the larger unions, and especially with the appearance of joint boards in the industrial unionism of the clothing industries, the versatile business agent has been replaced by specialized agents for administrative, personnel or organizing work. At the same time an effort has been made to professionalize the office by special pre-election or appointment tests of ability and character. Abuses of authority are most likely to occur where all these functions are centralized in one person and where the usual short term of office has been lengthened by re-elections or has been made, as in some instances by actual vote of the membership, a life tenure.

The qualities demanded of the office are peculiarly those of the business man—the ability to act quickly and bargain well rather than scrupulousness and delicacy. Since the union

rules are often not enforceable on all jobs, the business agent must be a shrewd compromiser. Incumbents tend to assume the mental outlook of the business man and the professional politician and to consider personal interests before those of the membership, the industry or the public.

Much has been made of the labor leader's isolation—physical, economic and emotional—from the rank and file, but such isolation is probably less characteristic of the business agent than of the national officers. For actually his tasks, whether as part time official of a small and struggling union or on the full time job, keep him in close contact with the ordinary union members. In most industries the business agent's earnings are based supposedly on the full time earnings of a skilled journeyman working steadily, and if defeated for reelection he is likely to return to the trade. Often, however, after experiencing the white collar type of employment he is not disposed to resume the status of a wage earner and is encouraged in his attitude by employers either directly through bribes and favors or indirectly through subtle forms of flattery. He is likely to spend much time consolidating his position by creating a machine and by practising favoritism or by seeking out alternative employment against his possible defeat for reelection. In industries characterized by the contractor system and requiring small capital he is likely to become a contractor. Business agents have been known to receive money from employers while still on the job and when defeated on charges to enter openly into their pay.

Nevertheless the problems of abuse arise not so much from the isolation of the business agent as from the nature of the industry and its reciprocal effects on the type of unionism. These abuses have been most glaring in the building industry. Its local character, the irresponsibility of the contractors who are the wage payers and their rapid movements from one job to another necessitate immediate settlement of grievances. Rapid changes in the technique of construction and in materials have tended to destroy standardization and uniformity of practise, so that much has necessarily been left to the judgment of the business agent. The business agents in this industry, since the time of their emergence in 1884, have had power to call a strike immediately. The discipline of the membership has caused them to answer the call to strike and to obey other orders even when the reasons were

not clear. Because of the intimate way in which the building trades are associated on the job, joint action among agents on a given building has frequently led to a development of power greater than that of any other group in the construction industry. The absence of any fixed price for the finished product has also contributed to this result. Occasionally the union members, aroused by exposures such as that of Sam Parks in 1903, have attempted to establish more effective controls over the business agent; but since this would entail actual visits to the job such efforts have been almost uniformly unsuccessful. Even when in 1920 it was shown that Robert P. Brindell, president of the New York Building Trades Council and business agent extraordinary, had built up a fortune of a million dollars largely through extortion, the unions involved made only slight changes in their methods of control.

In other industries where such abuses are comparatively infrequent methods of control are likely to develop through the supervisory and veto power of district and national officials; the lively interest of the rank and file unionists in shop committees, executive boards and local meetings provides another check. In larger unions, moreover, the business agent's position may be limited to job inspection and adjustment of complaints. In addition, the regulation of employment, the spread of standardization, the decrease of cut-throat competition in industry may be expected to raise the level of local union leadership.

BUSINESS CYCLES are a type of fluctuation characteristic of economic activities organized in the form of "business economy" or "high capitalism," to use the German term. They have a wavelike pattern—each cycle includes a phase of revival, expansion, recession and contraction.

These successive changes in activity spread more or less promptly over a large part, seldom over all, of the economic processes of a country. The cycles are recurrent, but not periodic. Their average duration varies in communities at different stages of economic development from about three to about six or seven years.

This list of features makes a thumb print which is useful in identifying business cycles amidst the welter of changes to which economic activities are subject. But a vivid impression of the part they play in modern life and the problems they present to economics can best be had from a historical approach.

The Development and the Discovery of Business Cycles. Trade crises must be as old as trade itself and must have affected the fortunes of increasing numbers as trading grew in social importance. The early crises of record were commonly attributed to what would now be classed as random causes, such as governmental aggressions, riots, wars or "acts of God." As economic activities became more highly organized, random factors continued to make business troubles; but new sources of difficulties appeared within business itself. For example the outstanding feature of the Mississippi bubble and the South Sea scheme, which ran their parallel courses to disaster in 1720, was a mania for speculation. In the later crises of the eighteenth century commercial miscalculations were held responsible in increasing degree. By the close of the Napoleonic wars it was realized that "commercial crises" are recurrent, and economists began to devise explanations which applied not merely to a particular case but to crises at large.

Gradually the problem of accounting for "periodic crises" expanded in scope. In 1833 John Wade suggested casually that "the commercial cycle is ordinarily completed in five or seven years, within which terms it will be found by reference to our commercial history during the last seventy years, alternate periods of prosperity and depression have been experienced." This idea occurred to others and spread rapidly. Economists who still wrote under the caption "crises" came to deal with the full round of cyclical changes. Thus the term "business cycles," or "trade cycles" as the English say, is a twentieth century rechristening of a nineteenth century discovery.

Sources of Information. Commercial crises were dramatic departures from the ordinary course of affairs which could scarcely be overlooked by the least skilful of observers. Hardly

less striking were periods of boom and depression. The earlier investigators of these phenomena harbored no doubts about their genuineness. Descriptive materials such as merchants, bankers and newspapers provided sufficed to show the facts which required explanation. What statistical data were available concerning bankruptcies, imports, exports, discount rates and the like seemed merely to make this common knowledge more definite.

As statistical data grew more abundant it became possible to attempt more penetrating inquiries. Yet efforts in this direction led to difficulties and doubts, for time series show several distinct types of fluctuations in combination. To pick out the cyclical fluctuations for intensive study was a difficult task. Indeed the question as to what constitutes a business cycle, a question which seemed simple when few but descriptive materials were used and those in a broad way, now became complicated. The statistical investigator had to develop a sharper concept of the cyclical component in the changes of a given series; he had also to discover what sort of whole the cyclical fluctuations of different series make up. These are problems on which investigators are actively working, spurred on by critics who hold that "the so-called business cycle" is a myth.

While reliance is now placed largely on analysis of the increasingly abundant statistical data the older type of descriptive material has not dropped out of use. On the contrary such materials have been collected more systematically than before and condensed into "business annals," showing the changes from year to year in the state of trade. Collections of this sort extend our knowledge of cyclical fluctuations over countries and periods for which the statistical record is scanty. And where the statistical record is fullest business annals are a useful adjunct to the analysis of time series.

Analysis of Time Series. Most economic time series show four distinct types of changes: secular trends, cycles, seasonal variations and random perturbations. Less definitely established are certain other fluctuations called by their discoverers "long waves" and "secondary trends."

The secular movements are ascribed to factors which influence an economic variable in some uniform or regularly changing fashion over periods of time which for present purposes may be defined as long in proportion to business cycles. Examples are the gradual decline in American canal traffic which accompanied the

development of transportation by rail, and the growth of the latter—a growth very rapid at first, then moderating its pace.

Swerving about a line of secular movements there may be several sets of wavelike fluctuations differing from each other in duration and presumably arising from complexes of causes which contain different elements. Thus Kondratieff, on analyzing a considerable number of the longest European and American time series, concludes that the capitalistic world experienced two and a half "long waves" between 1785-95 and 1914-20. The duration of these waves he gives as 40 to 60 years. Kuznets, using a larger number of series, finds waves which he calls "secondary movements" averaging not quite 25 years from trough to trough. Both of these results have still to pass through the process of critical testing by other investigators.

Seasonal variations arise partly from climatic and partly from conventional or institutional factors. Examples are the increase in coal consumption during the winter, holiday shopping in December and large dividend disbursements at the beginning of each quarter. In some series the seasonal variations are so prominent as to obscure all other fluctuations. When no regular seasonal change can be detected in a series the activity represented is presumably influenced by so many independent seasonal factors that they cancel one another's effects.

Random perturbations are as universal in their incidence as seasonal factors. Every economic process is affected at all times by a host of influences which cannot be classified under any other recognized head. When these many influences are not markedly unequal in magnitude and not closely connected by causal bonds they may be expected to offset each other so as to leave few detectable traces in a statistical record. At any moment, however, one or more factors having similar effects may rise to dominance in the constellation of random influences and produce marked perturbations in the net resultants of all the forces operating. Violent aberrations from the expected course of affairs are often plausibly attributed to a particular random cause such as a strike, a new law or a war. But the "expected course of affairs" is a vague concept. Analysis of a given time series over a period when no violent aberrations appear cannot determine what role the constellation of random factors is playing. And when some sudden break can be attributed to a definite cause it is impossible to say just how much of the ob-

served effect that particular cause accounts for.

Intervoven with the preceding types of fluctuations are wavelike movements which recur more or less regularly, with a time span longer than a season and shorter than that of the problematical secondary trends. In numerous series such fluctuations stand out boldly. In other series they can be traced by one on the lookout for such phenomena. In still other series they seem to be lacking. All recurrent fluctuations in individual time series with an average duration of more than a year may be called "specific cycles" to differentiate them from the general movements called "business cycles."

Even when cyclical fluctuations are readily discernible they are always shrouded by a veil of other changes—a mixed fabric woven in varying proportions of secular, seasonal and random changes, perhaps also long waves and secondary secular movements.

One of the obvious tasks of research is to draw aside this veil of other changes in order to see the cyclical fluctuations more clearly. The technique developed for this purpose consists in measuring and then eliminating such types of fluctuations as can be seized by statistical methods.

Current efforts toward isolating business cycles seldom go beyond computing and eliminating the secular and seasonal movements by methods which are described in the articles on these topics. Combined, trends and seasonals produce a curve which is usually characterized by regular wavy movements of a year's span superimposed upon smooth sweeps covering considerable periods. If long waves or secondary secular movements are found in a series and measured, an investigator may combine them with the secular-seasonal curve. But this is a stage of refinement not yet methodically attempted, although many empirical trend determinations presumably include secondary secular movements without the investigator's knowledge. Whatever the fluctuations independently measured, their values, in combination or by successive operations, are divided point by point into the corresponding values of the original data. The quotients, multiplied by 100 or treated as deviations from zero, are taken to show the cyclical-random fluctuations of the series.

Of course this stage represents but a partial segregation of cyclical fluctuations. How to press the segregation further by eliminating the random variations is one of the current problems.

Perhaps the most promising suggestion is the following: (1) After eliminating the secular trend of a series, its seasonal variations and any other type of fluctuation susceptible of direct measurement, break up the residual cyclical-random fluctuations into segments on the basis of the cyclical turning points, which can usually be located with some confidence on a chart. (2) Find the average value of the first segment, take this value as 100 and turn the series into relatives. This procedure applied to each segment in turn yields comparable figures showing cyclical-random fluctuations in as many cycles as the series covers. (3) From the relatives for successive revival dates, or for a few months centered on these dates, derive whatever average best represents the central tendency of the array. Make similar averages for the reference dates for successive recessions. In these averages the distorting influence of random perturbations will be attenuated generally in proportion to the number of cycles represented. (4) Elaborate the observations as far as desired by breaking the intervals between revival and recession and between recession and the next revival into fractions, computing averages of the relatives for each fraction and drawing representative averages from the array for each fraction, just as averages were drawn for revivals and recessions.

The number of cycles which a series must cover to yield fairly representative cyclical patterns depends on the character of the series and the character of the period covered. Frequently half a dozen cases or even fewer suffice to establish the general character of the special cycles found in a series; but of course an investigator likes to have more evidence at his disposal.

Specific Cycles and Business Cycles. Not all the specific cycles found in time series are systematically related in time to business cycles. For many economic activities have a rough rhythm peculiar to themselves, arising from technical circumstances not closely connected with the condition of general business. For example Warren and Pearson find a fifteen-year cycle in the purchasing power of farm prices for beef cattle in the United States. Pigou holds that in England "ten years seem to be, not merely the average, but also the markedly predominant" working life of machinery. Hence any period of active machine buying gives rise to subsequent cycles of a ten-year span in machine buying, although these cycles may run down gradually with the lapse of time.

To determine in what economic activities the specific cycles conform to business cycles is an additional task. One may proceed empirically, sorting the series into groups based on the timing of their cyclical turning points and then studying the interrelations among the cycles of the several groups. A more systematic and in the end a quicker method is to begin by drawing up a set of "reference dates" marking off successive revivals and recessions in "general business." Such reference dates may be taken from some time series believed to reflect changes in business tides. An index number of prices at wholesale might serve, or an employment index, or bank clearings in Anglo-Saxon countries. But uncertainty regarding the role played by random factors in any single series and the difficulty of finding fit series which have been maintained in trustworthy form for long periods of time favor the choice of a broader base. Business annals when carefully compiled seem to offer the safest guide, and they can be carried as far back in time as is required. The indications they give regarding the timing of revivals and recessions can be made more definite and checked by supplementary use of such time series as are available.

There is an element of unreality in giving precise dates for revivals and recessions in gen-

eral business; for these changes really take place during transition periods rather than at turning "points." But some set of bench marks is needed from which to measure the various turning points of individual series. The lack of uniformity in the materials on which decisions must be based makes it impossible to fix reference dates over long periods and in different countries in strictly consistent fashion; but if the dates are used merely as points from which to measure the leads and lags of different series this defect is not vital. The order in which the various series turn up or down is the important matter and it does not depend upon the dates chosen.

Equipped with a schedule of reference dates showing the time when each cycle in general business began, culminated and ended, an investigator can determine in what series the specific cycles conform in number and timing to business cycles. Further, he can make a second set of measurements showing the cyclical behavior of different series within the standard periods marked off by revivals and recessions; that is, he can take the turning points in general business, instead of the low-high-low points in each series, as the chronological basis for deriving cyclical patterns in the way described above. For many purposes this second set of measure-

STANDARD REFERENCE DATES FOR BUSINESS CYCLES, UNITED STATES, 1855-1927

EXPANSION		CONTRACTION		DURATION IN MONTHS		
REVIVAL	PEAK	RECESSION	TROUGH	EXPANSION	CONTRACTION	FULL CYCLE

Aug. 1924 to Oct. 1926	1926	Nov. 1926 to Dec. 1927	1927	27	14	41
AVERAGE DURATION						
19 cycles 1855 to 1927				25.4	20.7	46.1
13 cycles 1885 to 1927				22.8	16.5	39.3

ments, made on a common time schedule, is even more significant than the first set. Finally, an investigator can express degrees of conformity between specific cycles and business cycles in numerical terms, and classify all the series he uses according to "indexes of conformity" which run in practise from $+100$, indicating perfect positive conformity, through zero, indicating no conformity, to -100 , indicating perfect inverse conformity. Of course, in a theoretical inquiry, series which conform irregularly or not at all to business cycles require quite as careful attention as series which conform perfectly.

Half a dozen illustrations of special cycles and their relations to business cycles are provided by the annexed chart. In each graph a comparison is made between the average behavior of the variable within the periods marked off by its own cyclical turning points and within the periods marked off by the cyclical turning points of general business (standard reference dates). Seasonal variations have been eliminated from all these series except the wholesale price index, which has no regular seasonals. Secular trends also are eliminated from the "index of general business activity" compiled by the American Telephone and Telegraph Company; in the other series they are eliminated in part and in part retained. The process of turning a time series into relatives on the bases of successive cycle segments leaves undisturbed whatever trend is present within the time span of an average cycle, but excludes the trend from one cycle to the next.

All six series show well marked specific cycles. In three cases the specific cycles agree perfectly in number and closely in timing with business cycles. Bank clearings outside of New York City skipped the recession at the close of the late war, and the lawful-money holdings of New York City national banks skipped the revival of 1897. Yet the chart shows a close correspondence between the average cyclical movements of these series and those of general business. Quite different is the case of the one agricultural series. Flour shipments from Minneapolis have clearly marked specific cycles, a little longer on the average than business cycles. However, the relation in time between these specific cycles and business cycles is so irregular that when this series is chopped into segments on the basis of the standard reference dates the specific cycles almost cancel each other. Crop series commonly yield this result when similarly analyzed.

One example is given of an "inverted" pat-

tern. The lawful-money holdings of New York banks before the war declined in periods of expansion and rose in periods of contraction. Other examples of inversion are unemployment, bankruptcies and many records of commodity stocks, though by no means all.

In amplitude of cyclical rise and decline there is a marked difference between the wide fluctuations of pig iron output and the narrow movements of wholesale prices. More extreme contrasts would be provided by taking series of discount rates, stocks of commodities or net earnings on the one hand and retail prices on the other.

Finally, the present sample illustrates the variety of time relations between specific cycles and reference cycles. The specific cycles of bank clearings outside New York City, partly because of their marked intra-cycle trend, lead the reference cycles by 3.3 months at revival and lag behind the latter 2.2 months at recession. The specific cycles of pig iron production lead the reference cycles by 3.5 months at revival and are virtually synchronous with them at recession. Wholesale prices, on the other hand, lead a bit at revivals and at recessions. In lawful-money holdings of New York banks the inverted specific cycles lag some four months at revivals, decline for a short while and then have an uncommonly long advance. As for flour shipments from Minneapolis, the irregular time relations between the specific cycles and the reference cycles make it impossible to establish significant leads or lags. On the chart the two curves are arbitrarily centered at the same vertical line.

Business Cycles as Wholes. All the statistical analysis so far spoken of applies to individual time series taken one by one. To the theorist the finished results are merely raw materials useful in his effort to understand business cycles as wholes.

This effort has been likened to that of ascertaining changes in the general level of wholesale prices from quotations for individual commodities. The analogy is suggestive but there is a vital difference between the two problems. Price quotations for different commodities can be made into index numbers by some process of summation. But a mere summation of the cyclical fluctuations of time series representing different types of economic activities has no meaning. To understand business cycles it is necessary to understand the relations among the cyclical fluctuations characteristic of different

processes. Working hypotheses concerning these relations should determine what cyclical measurements shall be combined to get significant indexes and how the individual series or indexes representing different types of activities shall be used.

At this point the quantitative study of business cycles connects with earlier work. We have noted that efforts to explain the frequent recurrence of "commercial crises" began before any but the most meager statistics were available. Hence numerous "theories of crises and depressions" were developed by men in no position to test their validity by appeal to measurements. When the accumulation of data and the development of statistical technique had made a more searching type of work possible those who took advantage of the new materials and methods could avail themselves also of the old hypotheses, as well as of any fresh ideas they got while working with time series.

Leading Explanations of Business Cycles. These explanations may be summarized in three classes according to the nature of the causes stressed most heavily.

(1) Physical explanations run back to the idea of Jevons announced in 1875 that the activity of solar radiation controls mundane weather, weather dominates crop yields and crop yields dominate business conditions. The leading contemporary explanation of this type is Henry L. Moore's theory of eight-year "generating cycles." Moore holds that generating cycles are "the natural, material current which drags upon its surface the lagging, rhythmically changing values and prices with which the economist is more immediately concerned." As for their origin he suggests that weather cycles are caused by the planet Venus, which at intervals of eight years comes directly into the path of solar radiation to the earth.

(2) John Mills gave a "psychological" explanation of "credit cycles" in 1867. Among present writers perhaps Pigou lays most stress upon the emotional factor in business, although he recognizes that "industrial fluctuations" are probably due to a combination of several factors. When trade is active business men tend to become over-optimistic concerning their prospects. Hence they invest freely in industrial equipment. While this equipment is being constructed the active demand for products makes prices remunerative. But when a large part of the new equipment begins to turn out products prices fall and the error of optimism is revealed.

The new condition breeds an opposite error of over-pessimism which checks investment until the reduction of carried over stocks and the gradual growth of demand develop a profitable market once more and so generate a new wave of over-optimism.

(3) Institutional explanations trace business cycles to the workings of various economic processes: banking, saving and investing, producing and consuming, disbursing and using incomes, profit seeking and economic innovations.

R. G. Hawtrey's analysis of the cyclical impulses arising from banking runs as follows: When banks have large reserves they reduce discount rates and so encourage borrowing and business expansion. Once started an expansion mounts cumulatively until the growing requirements for cash created by active trade and large wage disbursements impair bank reserves. Then the banks raise their discount rates, thereby contracting loans and hence the volume of trade. Thereupon cash requirements become smaller and funds accumulate in the banks once more. Competition for the reduced volume of business leads the banks to reduce their discount rates and a new cycle begins.

John A. Hobson's "savings theory" makes business cycles an indirect result of inequalities in the distribution of income. In a period of prosperity large incomes swell so rapidly that the recipients cannot increase their personal consumption proportionately. An automatic increase in savings results. The investment of these huge sums brings about an increase in the equipment for making goods which exceeds the growth in the capacity to buy. A check comes when many of the new plants are finished and seek to market their products. Prices fall and large incomes are so reduced that over-saving ceases. Consumption then gradually overtakes production, restores profitable prices and starts a new cycle.

The modern theory of general over-production is best represented by Aftalion. Good trade leads to rapid increase of industrial equipment, then to an increase in the output of consumers' goods and finally to a decline in their marginal utilities. Meanwhile money is in active demand—its marginal utility tends to rise. These two changes combine to reduce the demand prices for consumers' goods, thus lessening the profits of business enterprises and checking the growth of industrial equipment. Depression sets in and lasts until the slow growth of consumers' de-

mand has restored a profitable market for the existing plants—whereupon the cycle repeats itself.

Spiethoff denies that consumers' goods or goods in general are over-produced. He attributes recessions to over-production chiefly of industrial equipment and of the materials from which industrial equipment is made. The construction, steel, cement and similar industries depend for their market upon capitalized income. When steel and cement are made into steel and cement plants they increase the production of steel and cement themselves, forcing down prices and profits in the equipment trades. As matters now go it is practically impossible to maintain for long a tolerable balance between the growth of capitalized income on the one hand and the growth of the industries in which such income is chiefly invested. A relative excess of capitalized income leads to expansion; a relative excess of the goods in which capital is invested leads to contraction.

The income theory is associated with the names of Foster, Catchings and P. W. Martin. If the goods sent to market are to be sold at profitable prices the incomes disbursed to buyers must equal the full selling value of the goods turned out, and buyers must use their incomes promptly in taking goods off the market. But in practise business enterprises do not pay out the full selling value of their products. When times are active they retain a considerable part of their receipts to add to working capital, to provide dividends in lean years and the like. Hence a period of brisk business gradually accumulates an excess of goods offered for sale over the purchasing power of the market. This malproportion might be prevented if producers' and consumers' credit could be expanded in just proportion to the deficiency in disbursed income, business and personal; but that is a feat of economic rationality which no banking system can yet perform.

Veblen and Leasure have organized their explanations around the theme of profits. An increase in the physical volume of sales does not produce a corresponding increase in wages or overhead costs. Hence profits rise and business men seek to enlarge their working funds. Their chief resort is to banks, which are as eager to exploit the favorable prospect as any other group of enterprises. Supported by the increasing volume of credit, the business public bids up prices, enters into heavy future commitments and enlarges its plant capacity. These develop-

ments support each other so that business expansion becomes a cumulative process which runs on until one or more of the internal stresses which it accumulates reach the breaking point. Sometimes the first factor to be overtaxed is the banks. Prosperity causes a larger volume of cash to remain suspended in hand-to-hand circulation, and so tends to reduce bank reserves. At the same time demand liabilities grow apace because the expansion of loans increases deposits. If the banks find themselves compelled to restrict the granting of further loans, or even to charge very high discount rates, this check will bring on a recession. Or prospective profits may be undermined by the encroachments of increasing costs of doing business. Though lagging behind wholesale prices, wage rates rise. It is difficult to prevent the efficiency of labor from declining after the élite of the industrial army has already been enlisted, and difficult to prevent an even more menacing decline in the efficiency of management when the rush of business interferes with careful planning. The one way to protect profit margins against increasing unit costs is to raise selling prices. For a considerable time this remedy works; but it has to be applied again and again. And there is an elastic limit beyond which it cannot be carried; for rising prices increase the volume of credit required by business and so add to the strain on the banks. Moreover there are important groups of enterprises which cannot raise their selling prices effectively, such as public utilities, contractors not working on a cost-plus basis, manufacturers who follow a fixed-price policy. And in every period of rapid expansion there are some industries in which the increase of plant capacity so outstrips the growth of demand that selling prices are forced down. Thus expansion itself sets going processes which reduce prospective profits in an increasing number of enterprises. But prospective profits, capitalized at the going rate of interest, are the basic security on which rests the towering structure of credits. The mere rise in the rate of interest, which accompanies the later stages of expansion, forces a downward revision of capitalized values. When to this is added an actual decline in the profits which are capitalized creditors begin to take alarm and call for reduction of outstanding debts. Thus the weakness of a minority of business enterprises sets in operation a new process—liquidation of indebtedness—which leads to recession. In turn, recession leads to contraction. Credit ratings are revised down-

ward; financial obligations are gradually cleared off or readjusted; unit costs are reduced faster than selling prices; and the bulk of enterprises gradually get into a position where their prospects of profits begin to grow brighter—thus laying the basis for a new revival and period of expansion.

Finally, business cycles are held to be a result of the changes in organization which are such a characteristic feature of a business economy. Schumpeter's "innovation theory" may serve as an example. Most business men are "routinizers"—systematic people competent to run affairs on customary lines. A few are "innovators"—restless, inventive, daring men whose imaginative minds are ever planning new schemes. Such men produced the "commercial revolution" by reorganizing European methods of production. By exploiting mechanical inventions they made the industrial revolution what it was and still is. Today they are devising ever greater corporate combinations, upsetting selling methods, launching novel products, developing new sources of supply and cultivating new wants. When a wave of innovation mounts, business has a season of hectic activity. Prices of raw materials and of finished products, the kinds of goods demanded by buyers, the competitive position of different enterprises, methods and costs of obtaining capital, financial alliances—indeed most of the elements on which business plans rest, go through a series of changes. These unsettled conditions create difficulties for the mass of routinizers. Failures increase, confidence dwindles and there comes a crisis, followed by a period of dull times. Dullness checks innovation because it prevents the disturbers of the business peace from getting the capital necessary for carrying out their hazardous schemes. Dullness also allows the routine business men to work out a passable readjustment of their plans on the new basis. But no sooner is quasi-stability re-attained and confidence restored than the innovators are again able to put some of their schemes into effect. Followed by a host of imitators they set going a new crop of changes, which multiply rapidly and bring on another crisis.

The various explanations sketchily presented here, and the numerous other explanations which might be cited, are not to be thought of as contradicting each other. Even from the viewpoints of the authors the differences consist mainly in emphasis. Each writer selects from the cyclical changes going on in modern society the process which seems to him of greatest im-

portance and analyzes that in detail. But he may also make elaborate use of theories presented with an emphasis other than his own. Thus Pigou, who stresses emotional aberrations of business judgment, can take account also of construction, monetary and crop factors; Schumpeter can utilize Pigou's analysis as a side line; and the profits theorists can comprehend any change which appears to affect prospective profits in a rhythmical manner.

This inclusive use of what were originally offered as independent explanations is especially congenial to statistical workers. The task of a theory of business cycles, seen from their angle, consists in finding out what cyclical fluctuations are characteristic of different processes, searching for explanations of the idiosyncracies revealed and tracing the connections among different processes. In seeking to trace these various connections they need and can consistently make use of working hypotheses concerning the numerous processes which are parts of the whole. So far as their effort succeeds it weaves the elements into a common pattern. The end result aimed at is not eclectic patchwork but a systematic account of all the relevant phenomena.

The Phases of a Business Cycle. A systematic account of cyclical fluctuations, taken seriously, becomes an analytic description of the processes by which a given phase of business activity presently turns into another phase. The obvious framework for such a description is provided by the successive phases of the cycle. Historical changes in the character of the phenomena, as well as advances in knowledge, have led to significant modifications in the scheme and names of these phases favored at different periods.

From crises, the first focus of attention, the interest of investigators extended to the subsequent depressions. Prosperity was recognized as a problem when it became clear that the causes of crises are to be sought among the developments of the preceding booms. Somewhat later began definite attempts to find out how business recuperates from depression. Thus the four-phase business cycle of prosperity, crisis, depression, revival, came to be accepted. The suggestion that the transition from prosperity to depression be subdivided into two phases, "financial strain" and "industrial crisis," making a five-phase cycle, encounters two objections. In numerous cycles the phenomenon of financial strain has been conspicuous by its absence; in

other cycles periods of acute financial strain have occurred within the phase of depression instead of during the transition from prosperity to depression.

Moderation in the violence of cyclical changes has led to revision of the old nomenclature. During the 1860's British bankers discovered methods of "panic financing" enabling them greatly to moderate the credit strains which had been a prominent feature of past crises. Arrangements which assured all solvent borrowers of bank accommodation adequate to their needs, though at a high rate of interest, put an end to panic fears. Adaptations and extensions of the peculiar British measures in other countries, in combination with other lessons learned from past experience, have given many of the later transitions from prosperity to depression so mild a character that the word "crisis" seems scarcely fitting. Nowadays the term "recession" is widely used. Only a recession of a severity now uncommon, like that of 1920, is called a crisis.

Corresponding doubts are beginning to be harbored about the terms "prosperity" and "depression." There have been cycles in various countries in which the phase of increasing activity has not reached the pitch which "prosperity" suggests and in which the phase of declining activity seems not to justify the use of so strong a word as "depression." As substitutes the terms "expansion" and "contraction" are used here.

Even the latter pair may prove to have no more than a passing historical fitness. Statistical studies of cyclical behavior reveal not a few cases in which important processes have shown no actual shrinkage during the contraction phase of mild cycles. A stoppage of expansion is observed, or merely a retardation in the rate of growth. If the many sided efforts now under way to control business cycles succeed gradually, this attenuation of cyclical fluctuations will become common. Then the terms "expansion" and "contraction" will be replaced by some other pair such as "acceleration" and "retardation."

Differences Among Business Cycles and the Task of Explanation. Business cycles, then, are not a fixed species but an evolving one. To the familiar notion that individual cycles differ from each other because each is influenced by a unique constellation of random influences must be added the notion that business cycles are subject to secular changes. Coming into existence gradually with a certain form of economic

organization, they have changed as this organization has changed. The geographical and the industrial scope of the oscillations has grown wider; their amplitudes have grown narrower. Needless to say this is a checkered development; but the trend is clear if one compares cycles separated by a century. Further, while the modern business world has a common pattern, every country has its own peculiarities of economic organization and development which affect its cyclical fluctuations.

The secular, national and random differences among business cycles have exercised not a little influence upon theoretical inquiries. The peculiarities of the case with which a writer is most familiar are likely to color his impressions of the general character of the phenomena, much as his personal idiosyncracies color his notions about human nature. The best safeguard against such misconceptions is study of objective records covering numerous cycles which occurred in different times and countries. Such study suggests that a complete theory of business cycles would explain not merely the tendency of all business economies to develop rhythmical alternations of expansion and contraction, but also the secular changes in the manifestations of this tendency, the differences among the cycles of different countries and the roles played by random factors. Though so ambitious a scheme may be visionary it is desirable to consider just what part of the full task any given theory essays to perform.

The following analytic description of a business cycle aims merely to sketch the leading features generally found in the recent cycles of such countries as the United States, England and Germany. It does not dwell upon the characteristic differences among the cycles of these countries, upon the secular changes which can be traced in each or upon the effects of random influences. Even the striking perturbations of the late war are passed over.

The Phase of Expansion. Since revivals are conceived to grow into periods of expansion, expansions into recessions, recessions into contractions and contractions into new revivals, a description of cyclical fluctuations may start with any phase. But whatever phase is chosen as the starting point, the business conditions out of which that phase arises must be taken for granted. How these conditions develop can be shown only by working forward through the cycle until the starting point is reached again. The present exposition breaks into the round of

events at the point where a revival has gotten well under way. How the revival started is the last question to be answered.

Among the fruits of revival are an increase in the physical volume of production and trade, fuller employment, an upturn in commodity prices, brighter prospects of profits, an advance in the prices of stocks, the prevalence of optimism, a desire to expand business enterprises, larger borrowings, heavier investments in industrial equipment and rising interest rates.

For a time each of these developments supports and stimulates the further progress of all the others. Thus the increase in physical production and trade enlarges the demand for labor and swells the stream of income even before wage rates rise. Large wage disbursements broaden the market for consumers' goods and so support the increase in production not merely of goods which families consume but also of the materials and equipment from which and by which they are made. These swelling demands push up the prices of the goods which are being bought freely and of the materials from which they are made. The greater volume of trade betters business prospects and makes men optimistic; the rise of prices reinforces these factors. Optimistic expectations of profits promote the further expansion of production and trade, the employment of more labor and the advance of prices. All these factors combine to encourage investment, which stimulates construction work, which adds fresh impetus to the demand for goods, the rise of prices, the employment of labor, the disbursement of incomes, the growth of retail trade and the optimistic spirit, thus returning through a spiral of reactions to heighten investment itself.

Once started, then, the expansion of business becomes a cumulative process. In the absence of unfavorable random factors, when well under way even in the face of such factors, the movement seems to generate momentum. Nor is there anything mysterious about this appearance. For in modern nations, where most people get their livings by selling services or goods for money incomes and then spending money for goods, everyone helps to make the market for everyone else. The more one man gets the more he buys of consumers' or of producers' goods, and so the more other people are able to buy of what he has to sell. Hence an increase of activity at any point in the whole organization tends to spread and, through a series of reactions, to intensify the activities with which it started.

The Phase of Recession. Because of this interdependence among economic processes, however, expansion in any one process cannot exceed certain limits set by the synchronous expansion in other processes. These limits are neither uniform nor rigid; for economic organization is a rugged affair which does not require precise adjustments among its growing parts. Yet, since there is no adequate provision for keeping a balance, in every period of acceleration the cumulative expansion of different processes is so uneven as to produce a series of minor checks. The difficulties which are overcome reappear or are succeeded by more threatening stresses, and soon or late the cumulation of favorable influences turns into a cumulation of business troubles.

Profits are the focus of economic activities in a business economy. A pervasive but mild check upon the growth of profits comes into operation when expansion reaches the stage at which most enterprises have as much business as they can readily handle with their existing equipment of standard efficiency and with the trained personnel at their disposal. Before this stage was reached every additional order secured at current prices had promised a more than proportionate addition to profits because it distributed overhead costs over more units without raising operating costs per unit. But thereafter unit costs rise. A further expansion of business now requires the use of substandard equipment, the breaking in of new employees, who are likely on the average to be less efficient than the old, and additional overhead commitments. Raw material prices, wage rates and interest charges mount rapidly when business enterprises of many kinds are competing eagerly for supplies, labor and loans. Also it becomes difficult to maintain a high standard of operating efficiency when overtime is common, when discharge is a trifling penalty and when everything must be done in a rush both in the office and in the workshop.

The sovereign remedy for increasing unit costs is to raise selling prices. That remedy can be applied without checking the volume of trade while people expect the rise of prices to continue; but there are enterprises which cannot resort to it readily. Public utilities whose charges are regulated by governmental commissions, contractors who have taken long jobs for fixed sums and makers of goods which are sold at widely advertised prices cannot pass on the mounting costs to their customers promptly and in full. Thus a not insignificant minority of

business enterprises may find their prospective profits shrinking as expansion runs on.

Another way to take business advantage of rising demands and to counteract rising costs is to increase plant capacity and to make the new plants more efficient than the old. That plan contributes to the activity of business for a time, but presently encounters difficulties. A wave of expansion usually brings an increase of contracts for new equipment before the old equipment is all in use; for business men try to anticipate their opportunities. The demand for new business buildings, factories, machinery, rolling stock and the like depends less on the physical volume of production than on changes in this volume. Any check in the rate at which the physical volume of business is growing will bring a positive decline in the contracts for new equipment. Then the equipment trades suffer, and all the more if, as is likely, the plants which themselves make steel, cement, machines, etc. have extended their facilities.

Such a check can scarcely be avoided as business is now conducted; for it is not possible to forecast accurately the growth in consumers' demand for all types of commodities and to adjust to this growth the expansion of industrial equipment, all of which depends in the last resort upon personal consumption for its market. Of course the equipment trades themselves give a powerful impetus to retail demand for commodities while they are disbursing wages for the making of goods which are not sold through retail shops. But when the new equipment is ready for use and begins adding to the supply of consumers' commodities offered for sale, not all the investments will prove profitable. Cases of "over-production" or "under-consumption" occur in every cycle. If they prove numerous they give rise to an impression that industry is "overbuilt" and check new orders for equipment. In any case it is not likely that the growth of physical demand for goods will long maintain the rapid pace characteristic of the early stages of expansion. All the other difficulties accumulating tend to moderate the rate of growth and so to produce acute difficulties in the equipment trades which will augment whatever troubles give rise to the check.

Meanwhile the intricate task of financing the swelling volume of trade at rising prices is becoming a problem. The best available data indicate that Americans spend some 50 to 60 percent of their money incomes at retail shops. Also it appears that individuals and business enterprises

together "save" sums which average some 15 percent of the national income—that is, they spend this proportion of their net receipts for income bearing goods. There remains a considerable slice of income for rents, personal service, taxes and miscellanies. To maintain business activity the flow of incomes to individuals and from individuals to retail shops must expand with the dollar value of the consumers' goods flowing into shops for sale. At the same time the flow of "savings" from individuals and business enterprises must be kept growing at a steady pace, or the enterprises which make industrial equipment will suffer a slump.

It is argued that the whole congeries of business enterprises cannot long disburse as income sums which exceed the value of the goods they produce, and that if they disburse any smaller sum, part of the goods they sent to market must remain unsold or be sold at a loss. Prosperous enterprises do not disburse the full value of what they contribute to national production; they require larger working capitals and they deem it wise policy to accumulate reserves, which may not all be invested promptly in ways which sustain the demand for goods. Hence there is danger that the flow of individual and corporate incomes will lag behind the volume of goods seeking sale.

This deficiency of current income may be made up by bank loans, which put additional purchasing power at the disposal of the public. But that raises a new question of adjustment. If the banks extend their loans too freely the chief effect may be to accelerate the rise of prices and so presently to recreate the difficulty of finding enough purchasing power to buy all the goods sent to market. If the banks do not lend enough, or if they do not distribute their advances among different classes of buyers in the proportions required by business needs, some section of trade will suffer. Economists who stress this line of analysis commonly hold that consumers' incomes require supplementing by bank credit on a larger scale than is practised.

There remains the question as to how far the banks can go in furnishing the community with the additional credit required by expanding trade and rising prices. An increase of loans leads to a more or less equivalent increase of deposits and notes. While reserves are usually high in proportion to demand liabilities at revival, the ratio declines in the course of expansion, not only because deposits and notes grow with loans but also because the public keeps a

greater volume of coin and paper money in its pockets and tills when wages are high and retail trade is active. Banks raise their discount rates; but that does not check promptly the demand for loans. They may get additional gold. But no matter how the banking system is organized there are limits below which it is not safe to let reserve ratios fall. When these elastic limits are approached the banks must discourage new applications for credit by very high discount rates and also set very exacting credit standards for new loans or even for renewals. If many enterprises cannot get loans at rates which leave a margin of profit business expansion will cease and there may be an epidemic of bankruptcies.

Although the preceding list of adjustments which must be maintained among different processes is not complete it suggests that, in the process of expanding, the business system may develop any one of numerous disorders. Neither business history nor business statistics supports the view that the decisive break always comes about in the same way. The sequence in which different time series reach their highest points and turn down varies from recession to recession. Usually several stresses seem to be accumulating during a period of expansion and the only question is which will overtax the factors of safety first. Random influences, such as harvest fluctuations, business conditions in foreign countries, the pet miscalculations of the day and the like, seem to exercise a considerable influence upon that event. And there seem to be secular changes in the character of expansions and recessions. Certain of the wilder excesses which characterized early booms seldom attain prominence today. But the fundamental difficulty remains of keeping all the important processes of a business economy duly adjusted to each other in a period when all are expanding. The more one studies the variety of cyclical patterns characteristic of different processes and the intricate ways in which different processes affect each other the more remarkable it appears that phases of expansion sometimes last several years. Two years is the average term in the United States, though four years was approached during the Civil War and again in the years 1915-18. In European countries the average duration exceeds three years, and periods of expansion outlasting four years are not uncommon.

Once a recession starts it commonly proceeds faster than does a revival, especially when the expansion has been accompanied by a

marked growth of interlocking credits. A few conspicuous bankruptcies may alarm creditors and set them pressing for the prompt settlement of their claims. Unless the banks are able to re-assure every solvent enterprise that it can get whatever accommodation it is entitled to, the recession will degenerate into a crisis or a panic. Granted this assurance, however, there may be little evidence of financial strain. Indeed, if the preceding phase of expansion has not reached the proportions of a boom and if the banking system is well organized and wisely managed, the recession may be as mild in character as are most revivals.

The Phase of Contraction is in many respects the reverse of the phase of expansion. Optimism gives way to pessimism, prices fall, production shrinks. In this general decline of activity there are significant differences of degree.

Consumers' demand, particularly for non-essentials, falls off appreciably in consequence of shrinking employment, the gradual spending of individual hoards and balances and the reduction of many non-wage incomes. Merchants require smaller stocks and cut their orders more than sales fall off. A similar policy is followed by other enterprises. Thus the reduction in volume of trade is amplified stage by stage as it travels back through wholesale dealers to manufacturers and producers of raw materials. Particularly severe is the decline of orders for new industrial equipment. Few enterprises care to sink money in extensions and betterments while most existing plants are either operating at but a fraction of their capacity or standing idle. Of course these changes react upon one another. Every reduction in production means less employment, less wage disbursements and thus less ability to buy at retail, still less production and less employment.

Similar differences mark the decline in prices. Wholesale prices fall faster than retail, the prices of producers' goods faster than the prices of consumers' goods and the prices of raw materials faster than the prices of finished commodities. The prices of crops may not follow this course because of harvest conditions; raw metal prices show the market conditions best. Wage rates (not wage disbursements) and interest on long time loans decline less than wholesale prices, while discount rates and common stock prices decline more. The one important class of prices which commonly rise in contraction are the prices of high grade bonds.

These developments reduce the profits of

almost all enterprises and bring deficits to many. The number of bankruptcies usually grows larger in contraction than it was during recession, although the average liabilities decline. Losses must be written off and reorganizations submitted to. With the reduction of inventories, current accounts and payrolls, less working capital is required and bank loans shrink.

As in the phase of expansion, so in that of contraction, there is an early period when every change seems to work in the same direction. One shrinkage forces others and is made more drastic by roundabout reactions from its own effects. But in the later phase as in the earlier the concatenated changes presently begin to raise obstacles to their own continuation.

The Phase of Revival. As unemployment increases and retail trade declines men have less money left in their pockets and shops need less in their tills. Idle cash accumulates in the banks and flows from the country districts toward the great financial centers. Combined with the net decline in bank loans, this flow raises reserve ratios. Discount rates fall very low, call rates lower still—sometimes so low that there is a margin of profit in buying gilt edged securities with borrowed funds. Such a condition in the leading money markets presently reinvigorates the demand for stocks and bonds. The stock market often revives in this way while general business is still at low ebb. An increased demand and rising prices of stocks are hailed as an encouraging sign.

Meanwhile the difficulty of making profits has put pressure upon business managements to improve their practise. The wastes, big and little, which often creep in during the rush of prosperity are discovered and eliminated. The reduced volume of business can be handled with the best of existing equipment and the most efficient personnel. There is plenty of time to supervise current operations closely, and also to devise plans for heightening efficiency. Overhead costs are in many cases cut by financial readjustments and operating costs by the fall in the prices of materials as well as by more skilful management. In some cases these changes are sufficient to restore a not unsatisfactory rate of earnings even while selling prices remain low.

An abundance of loan capital to be had at moderate rates has somewhat the same effect upon construction work that it has upon the demand for securities. Building materials can be had cheaply, building labor is eager for jobs, contracting firms will figure closely, prompt

deliveries and prompt construction can be counted on. Even though the current demand for new housing or equipment is slight, investors are found who think it well to anticipate revival and build while work can be done at low costs and long time financing arranged on easy terms.

Even the business in consumers' goods must presently look up. When times are dull retail merchants let their stocks run as low as they can without losing too many sales through broken assortments. This possibility of reducing stock was one of the factors which had enabled them to cut their purchases for a time more than their sales fell off. But once their stocks are reduced to the minimum of safety they must order at least as much as they sell. This means some increase of business for wholesale and manufacturing concerns. Indeed, if the rate at which their sales are shrinking becomes smaller, retailers must order more than they sell. Thus the mercantile demand for consumers' goods may begin to increase at the same time that retail sales are still contracting.

Also there are physical reasons compelling an expansion of consumer demand for certain types of goods. Shoes, clothing, house furnishings of many kinds can be kept in use a longer or shorter time according to the state of peoples' pocket-books. When hard times come many families economize by using these semi-durable goods as long as possible. Hence the demand for such articles falls off more in the early stages of contraction than the demand for staple groceries. But the time comes when an increasing number of the old articles are literally worn out. Then the indispensables at least must be replaced, if money or credit can be had in any wise. And that means another fillip to trade.

A similar observation applies to industrial equipment. Under pressure of hard times repairs, upkeep and renewals may be neglected for a while, not to speak of extensions and betterments. But that can be but a temporary policy. Whatever equipment is used must be kept in running order. The more it is neglected for a time the more work must presently be given to repair shops and equipment houses. Even the hardest pressed and most conservative enterprises are forced into this policy, if they stay in business. The more enterprising in trades which have been growing rapidly sometimes grasp the breathing spell of a slack year to build anew, planning to "junk" their old plants when the more efficient equipment is ready. Thus while

the equipment trades may have an exceedingly lean season they are sure of some increase in business after a while.

Nor can prices keep on falling rapidly for an indefinite time. In the face of threatened bankruptcy an embarrassed house may sacrifice accumulated stocks for what can be had. But men will not buy materials and make up new supplies unless they can get back at least their operating costs. These costs in turn are aggregates of prices, including the prices of labor, and it is difficult to beat them all down. Nor can the still more resistant overhead costs be left out of selling prices for long without disastrous consequences. As prices get lower and lower the rate of decline flattens out. Buyers see less gain in holding off for still better bargains, and begin to fear they may wait overlong and get caught on a rising market. The first sign that the low point has been reached in any line is likely to bring out a flood of orders and to encourage other sellers to resist further concessions.

Business sentiment also becomes less pessimistic. As the liquidation wears on the worst becomes known and proves less serious than many had expected. Bankruptcies grow fewer again; everyone realizes that others are being cautious; the majority of enterprises have proved their solvency; outstanding debts have been reduced. Confidence slowly revives, and men begin to remind each other that every past period of depression has been followed by a revival. How soon business will turn the next corner becomes the question of the day.

None of these encouraging developments has great momentum. Though each favorable change reenforces the other elements of strength, unfavorable random or secular factors may check one slight improvement after another. Thus the phase of contraction is sometimes prolonged in a most discouraging fashion, as has been the case in England, for example, since 1921. In the United States the depression of 1873-79 dragged on for nearly five and a half years, whereas the longest period of expansion in times of peace since the 1850's has not exceeded three years. But cyclical developments of a favorable cast keep cropping up. The time comes when they are not offset by "disturbing causes," or when they are reenforced by favorable developments from outside the realm of business. Then a revival makes itself felt and a new cycle begins. On the average in this country from 1855 to 1927 the phases of contraction lasted some twenty or twenty-one months as

compared with twenty-five months for phases of expansion.

BUSINESS EDUCATION. A consideration of any form of vocational education commonly proceeds upon the mistaken assumption that such training is a comparatively new social undertaking. It is thought of as instruction in doing, which in recent years has replaced in some measure instruction in culture. The error in such a view lies in an unduly limited conception of a vocation which subordinates it to a secondary place in life, makes it somewhat, if not wholly, antithetical to culture and confuses it with the specialized occupationalism of recent times. Yet a vocation, as John Dewey said, "means nothing but such a direction of life activities as renders them perceptibly significant to a person, because of the consequences they accomplish, and also useful to his associates." It follows that so far in the past as there was training calculated to aid in rendering life activities perceptibly significant and socially useful there was training in the "business" of practical and social affairs. That such a training is old in race history is evidenced by the instruction in tribal traditions, customs, rituals and tabus with reference to such practical matters as work, war and propitiation which is found among all primitive peoples. The folkways, which are the "right ways," of carrying on the arts of life are handed on from generation to generation.

It was when making a living by business became an outstanding part of the business of making a living that business education in a more definite sense became distinguishable from other vocational education. We may look for the beginning of business education in this restricted sense wherever an economic system based on the effecting of profitable transactions is first to be found. The experiences of the ancient Egyptians, Assyrians, Persians and Phoenicians were first paralleled in modern times in Italy. There is evidence that at least as early as the fourteenth century not only was the practise of commercial arithmetic and accounting well developed in several of the Italian cities but that there was also a literature upon each of these subjects.

The characteristic mediaeval form of business training was apprenticeship. Apprenticeship not only trained in technical skill; it was also an institution designed to give candidates for membership in the guilds the ability to carry on business in a difficult economic and social environment. The problems of a business man, multiplied by the expansion of the business system, were already complex for the mediaeval craftsman. Within shop or store customers must be dealt with, materials bought, production skill had or hired, satisfactory relations with employees attained and capital needs met. Moreover the ordinances of the town relative to wages, discipline, conditions of work, quality of wares and many other matters had to be understood and their provisions met. Apprenticeship prepared the novice for the carrying on of business in this complicated environment partly by formal direction, partly by precept and partly by intimate contact with the life of the master. It continued to be the most significant form of education for business until with the application of steam to industry the machine became more important than the artisan.

With the displacement of the guild system new and more restricted forms of business education developed. The earliest commercial schools and the most advanced types of modern business schools are to be found in Europe; but it is in the United States that business education has developed most extensively. The characteristic forms and the widespread adoption of business education in America were conditioned by the rapid expansion of industry in the nineteenth century. Mass production, the new market created by the tremendous westward movement of population and a large volume of business transacted with distant customers made necessary a vast amount of what have been called the "facilitating processes" of business. Letters had to be written, transactions recorded, extensive calculations of many sorts made. Calculation, accounting and communication were called upon to function as they had not been called upon before. This work did not demand the daring, intelligence or initiative needed by the organizers of expanding trade. What was required was accuracy, exactness and care in the performance of specialized clerical tasks. To provide these habits and skills there appeared—at first in a primitive form and later in a highly organized way—the private commercial school often inaptly called the business college.

Itinerant "penmen" played a part in this development and there are various claims to the honor of founding the first school, but the year 1853 opened a new period in the movement. In that year Bryant and Stratton formed a partnership which developed into a plan for a chain of schools with a unit in every city of over 10,000 population. Uniform textbooks and interchangeable scholarships were to nullify the student's risk in moving before a course was completed. Although the chain did not achieve its purpose before it fell victim to opposing forces, its plan of organization was widely imitated. The success of the private schools led to vigorous demand for commercial training at public expense. Although a beginning in this direction was made in Boston, Philadelphia and St. Louis not long after the middle of the century, it was not until the nineties that the important growth of commercial work in the public high schools occurred.

To the forces already indicated the invention of the typewriter proved an important addition. Following the patenting of various "typographers" the typewriter became a practical tool in the seventies. English systems of shorthand, already widely used in America for court and literary work, had been of less use to business. After a period of experimentation in which the typewriter proved its practicalability, business seized upon it for use in combination with stenography. Courses in the use of the typewriter and in stenography as phases of training for business communication soon came to out-rank all other types of secondary business courses except bookkeeping. Registration in high school commercial courses increased from 15,000 in 1893 to more than 75,000 in 1900, this increase being almost three times as great as the increase in high school enrolment during the same period. At the turn of the century there were two well developed agencies in business education in the United States, the privately operated commercial school and the commercial course in public high schools. The spirit and in large part the form of the second were in imitation of the first.

In the succeeding years these agencies have expanded in various ways while certain new ones have attained prominence. In private commercial schools the growth has been chiefly in numbers, with the greatest expansion in 1920 when there were approximately 336,000 students enrolled. Since that time there has been a steady decline, the most recent figures indi-

cating that there are about 188,000 registered. The curriculum continues to emphasize book-keeping, stenography and typewriting, but telegraphy has been included by many schools and there are also courses in selling, advertising and other subjects in imitation of curricula of the collegiate schools of business. A considerable number of private schools purporting to be of collegiate level have sprung up and many of the older commercial schools are including "university" or "college of commerce" in their titles. There is a further tendency among these schools, many of which have always been under criticism, to seek the approval of state departments of public instruction or other accrediting agencies. Such indirect regulation usually effects an improvement in curricula and methods.

Business training in the public high schools has in the last quarter of a century grown to enormous proportions. Toward the close of 1929 a report of the United States Bureau of Education stated that of approximately 1,000,000 students enrolled in business courses in various types of schools two thirds were in the public high schools. Between 1922 and 1928 there was an increase of 72 percent in the enrolments in commercial subjects offered in these institutions, bringing the total so enrolled to 17 percent of all public high school students. Two thirds of these are girls and the proportion of girls is increasing. While a great majority of high schools offer a four-year business course, a two-year course is common. The high school has also developed new departments through which it gives commercial work: high schools of commerce devoted solely to business teaching now exist in a number of cities; high school evening commercial courses are common; short intensive postgraduate technical courses are available in some places. High school commercial courses in general still represent mass production methods applied to the clerk making which the early "penmen" found profitable. But investigations which have disclosed that much of the training has been misdirected and that pupils do not find or remain in the type of work emphasized in the courses given have already led to some reorganization. There is a new emphasis upon a generalized clerical course and upon retail selling; training for the latter is often given in cooperation with department stores. Of broader purpose is the effort of a few persons to reconstruct the work more fundamentally, to make of business teaching in the secondary schools a device for realistic study

of modern economic and social culture. A degree of success resulting from these efforts is shown in the increased interest in social sciences, in business curricula, in the improved textbooks for this work and in the growing demand for college graduates as teachers. Business teaching in the high schools is molded chiefly by a few universities, by teacher training in the normal schools which, however, is recent and limited, by the activities of the federal Bureau of Education and of the federal Board for Vocational Education and by teachers' association meetings.

In the past decade new agencies have become important in business education. One of these is the correspondence school which, with the exception of correspondence extension divisions maintained by a few universities, is a private enterprise like the business college. These schools prepare an educational product, usually packaged in a set of texts or a series of printed lessons or both, which they sell through advertising and personal solicitation. Some such schools offer general courses; others provide specialized training almost as varied as human occupations. A second agency is the company school formerly called the corporation school. Such schools established by business concerns under their own direction are effective in giving detailed instruction in the needs of a particular business.

The collegiate school of business is undoubtedly the most noteworthy of the more recently developed institutions for business education. Its growth during the past ten years has far outdistanced that of all other similar institutions. Enrollment in business curricula in colleges and universities has grown from about 9000 in 1915 to about 60,000 in 1930. In contrast to the situation in secondary schools six out of seven of the students are men. Such schools are parts of colleges or universities, paralleling in university organization schools of law and medicine and to some extent animated by the desire to give similar status to the practise of business. In a sense they grew out of the agricultural and engineering schools which emphasize the production aspects of business. The increasing competition of the second half of the nineteenth century which centered attention on the organization and directive features of business stimulated the appearance of collegiate schools of business. The first school of this type was the Wharton School of Finance and Economy established at the University of Pennsylvania in 1881. No other was founded until 1898, when both

the University of Chicago and the University of California announced such schools. There are now between 180 and 200 colleges or universities with some formally recognized business school or unit, most of which are in origin offshoots of departments of economics. Two schools, those of Harvard and Stanford, operate solely on a graduate level; others are chiefly undergraduate schools, but those affiliated with universities usually provide some graduate work. Harvard University and the University of Chicago have been prominent in planning curricula and in producing teaching materials.

The collegiate school of business faced many difficult problems during its distinctly experimental period of growth. It had no curriculum unless it was satisfied to imitate secondary schools; it had no teaching material and no properly trained instructors; the level upon which work should be given had to be determined. There were also difficulties of adjustment to other university divisions, particularly the departments of economics. Relationships with secondary commercial schools had to be established, and an intelligent contact between the new schools and business required development. By no means have all of these problems been solved. An underlying problem of organization remains—that of a social versus an administrative outlook. Most schools have frankly assumed an administrative point of view, but while some have interpreted this to mean chiefly a study of internal control methods others have included a consideration of the social incidence of business and even of its social responsibility. Most schools waver somewhat indefinitely between the two views. The critics of the collegiate school of business believe that as it develops teaching material and a staff distinct from departments of economics its spirit is narrowed and its work made more technical. Its more optimistic friends see in it the source of a new realism for economic study and an opportunity to give to business a more social outlook as well as a better administration. Certainly its vigor, its popularity, its contact with reality and its obvious relationship to a major social interest make it a force of great consequence in the development of higher education and possibly of social organization.

In Europe special commercial schools had a longer history. They sprang up in older commercial centers under the auspices of merchants' organizations or of private enterprise and later were incorporated into state or municipal systems of instruction. In England, however, spe-

cialized commercial education did not develop until the end of the century. E. J. James stated in 1893: "It is not far from the truth to say that there is no such instruction given in England at all." Public commercial education in that country was made possible by the Technical Instruction Act of 1889 which gave local authorities power to raise money for the purposes of technical instruction. The chief agencies at present are the so-called continuation schools, attendance at which is voluntary on the part of those leaving the elementary schools and which make provision for both junior and senior commercial courses. The private commercial school also flourishes in England and in contrast to its position in America appeals to a more exclusive group than do "the provided schools." Training of university grade was first undertaken in Birmingham in 1901 and is to be found usually in a three-year course in some of the universities. In France there is some commercial instruction in schools of primary and intermediate type. So-called superior schools of commerce were recognized by official decree in 1890. Most important of the higher schools is the *École des Hautes Études Commerciales*, which was established by private enterprise in 1820 and later taken over by the Paris Chamber of Commerce.

The history of special commercial schools is somewhat different in the newer states of Europe, established at the time when the rapid economic development of the nation had already become the prime concern of the statesman. After 1870 Germany built up a system of higher technical schools which included the *Handels-hochschule* type for advanced training in business. The latter provide graduate work in social economics as well as in business administration; in some cases they offer better courses in empirical and statistical economic disciplines than those available at the universities prior to the post-war reorganization. Below the *Handels-hochschule* are the elementary and secondary commercial schools including the commercial form of continuation school and a variety of types established by states, municipalities and private enterprise. The courses in these schools vary in length from one to three years. Similarly in Italy the trend has been to work downward from the top rather than upward from the bottom. Modern commercial education began with the establishment in Venice of a Commercial Institute of university grade in 1868. Later a number of other higher commercial schools

were organized. These greatly influence the types of work done in the "complementary schools," the "commercial schools" and the "commercial institutes."

Of the post-Versailles new countries Czechoslovakia is foremost in vigorous expansion of business education. Before the war such education developed to some degree against the definite opposition of Austria; following independence in 1918 a large number of commercial academies, apprentice continuation schools and two-year business schools were established. The Graduate School of Commerce was founded at Prague in 1919 by a law which stated that its purpose was "to offer to students an advanced training in business and economics so that they may become . . . the organizers of the economic life of the Republic." This statement of the role of an advanced school of business is curiously in line with the most sanguine expressions of opinion that have been put forward in the United States.

BUSINESS ETHICS. The ethical standards of business have until recently been determined by external agencies. For centuries the church was the chief critic of business methods or, as in Calvinism, provided business with its apologies. Later the state, often at the request of business men themselves, made business ethics coherent and effective in the form of legislation and adjudication. During the last century, however, church and state have failed to keep pace with the changing methods and growing complexities of industry and business, while business men themselves have indicated a willingness and capacity for that self-government which is one of the most characteristic features of present day social phenomena.

The development of business ethics was preceded by the rise of professional ethics, especially in law and medicine. Although professional and business ethics are sufficiently similar to suggest mutually fruitful and provocative problems, there is danger of making the analogy "walk on all fours" to the detriment of both. The professions are engaged essentially in furnishing services, whereas business deals largely in goods; in business sound credit arrangements and fair profits can be emphasized to a greater degree than is compatible with professional practise. The failure to appreciate these distinctions may encourage professional men and others to develop a supercilious attitude toward business practises, a view frequently acquiesced in by business men themselves. The development of business as well as professional ethics, however, is a part of the modern pluralistic social autonomy participated in by churches, labor unions, fraternal organizations and other social groups.

The more obvious problems in business ethics arise in connection with misrepresentations such as misleading advertisements and labels, with trade "piracy" adulterations and substitutions, commercial bribery and excessive "treating," false assertions regarding company affiliations or the source of goods or the process. Many problems in business ethics develop out of the structure of business and the functions made necessary by it. If the corporation is the warp of the business fabric, then the trade association may be likened to the woof. Wholesalers and retailers have been trying through trade associations to maintain their distinctive functions, emphasizing "legitimate" trade channels as opposed to the chain store and mail order house. Price policies involve the ethical prob-

lems of price cutting, "resale price maintenance" and discriminatory price schedules under the guise of "trade discounts" or "classification of customers."

The incidence of such practises is not confined exclusively to the purchaser-consumer; the self-damage to the trade as a whole is frequently as serious as it is unrecognized. Hence business ethics takes into account the harm done to the competitor, who has no redress in the courts and who in order to survive must frequently stoop to the tactics of his rival. Furthermore, business ethics becomes identified with sound economic policy: honest cost accounting, adequate and accurate business knowledge, sound credit arrangements and the necessity of securing a fair profit. Whereas the law and morals attach particular significance to motives, business ethics emphasizes the effect of business practises and condemns an ignorant competitor as much as it does a wilfully dishonest one.

In the United States the conscious development of business ethics by business men themselves consisted a decade or two ago in the formulation of so-called "codes of business ethics." Although many of these declarations were only vague generalities or hypocritical camouflage, they were symptomatic of a movement toward improved business relations and have more recently reflected the facts as well as the norms of business. The *Principles of Business Conduct*, a pamphlet distributed by the Chamber of Commerce of the United States, serves as a model to various businesses, especially to trade associations, in applying the spirit of the code to their own particular conditions. Similarly Rotary International has sponsored a code. But such codes at best are mere constitutional frameworks; to function effectively they need amplification and interpretation with reference to particular situations. A supreme court of business and subsidiary arbitration boards are as necessary to business ethics as an even more active Chamber of Commerce with its constituent local branches.

The Federal Trade Commission was established in 1914 to take administrative jurisdiction over cases of "unfair" business practises which did not ordinarily fall within the scope of constitutive law. For a number of years the commission proceeded against individuals or corporations in much the same manner that had previously characterized the activities of church and state. Within the last four years, however, the commission has been encouraging various

trade groups to endorse or condemn current trade practices; the commission then uses these "submittals" as the basis for its subsequent activities. The Department of Commerce has also induced business groups to assume responsibilities which the government could not appropriate without becoming paternalistic and which business men hesitated to undertake because of the fear of government disapproval.

A Better Business Bureau operates in each of over fifty cities in the United States. These bureaus, an outgrowth of the Vigilance Committee of the Associated Advertising Clubs, are financed by merchants and bankers through voluntary subscriptions. A merchandising section checks on advertising claims by following up customers' complaints and by sending out its own shoppers. A financial department is also available to investors, prospective or suspicious, to assist them in distinguishing investments from speculations and frauds. Bulletins are published periodically, reporting quite frankly and in detail the activities and findings of the bureaus, while a number of newspapers give the subject general publicity. Through such agencies business has been setting its house in order, especially as regards the rights of the consumer-purchaser.

Since investment banking occupies the key position in the modern business structure the development of ethical standards in this field is of particular importance. Each investment issue is sufficiently large and unique to warrant a separate ethical analysis, especially as regards fixing the responsibility for its security. The obligation to develop public confidence and financial stability, common to investment and commercial bankers, represents values formerly associated only with artistic achievements, political stability and spiritual immortality. Whether the banker can retain his hold on social confidence depends on his willingness to assume the accompanying responsibilities: determining to what degree an investment house should control the management of a company which it finances, and to what extent reliable and accurate information as to the business should be imparted to others, especially to prospective investors. The financial structure of corporations frequently determines their fate and vitally affects the fortunes of creditors, stockholders, management and workmen. The caveat emptor rule, seriously questioned in the field of marketing, may be even less defensible in the field of investment, where exploitation may lead to an ex-

cessive and ruinous appropriation of the savings of many people and the wrecking of their faith in the business structure.

The speculative values of new or reorganized business enterprises soon become tempered into investment values through the agency of an "exchange." The New York Stock Exchange has developed a constitution and rules which are probably more strict than could be attempted by legislation, since legislation if carried to that extent would have to apply generally to all business, large and small, a standard of conduct which is probably impossible of achievement beyond the restricted membership of the exchange. Through the agency of the exchange the capital values of corporations become objective and minutely measurable, thus affording a scientific basis for determining the ethical as well as the economic and business problems which arise.

The self-consciousness of trade interests, exhibited in corporation and association activities and expressed in principles of business ethics, is a social phenomenon analogous to the guild movement of the later Middle Ages. Whereas the mediaeval guild, however, was essentially local in character, with a restricted and yet compulsory membership, the trade association is generally national in scope, with its membership on a voluntary basis and with a consequently less compact organization. The guilds' endeavor to control the product from source to final sales resembled the vertical integrations achieved by the modern corporation. At the time of the guilds, however, national governments and a common law had not yet arisen; hence the guilds filled a very definite need for the protection and encouragement of industries and commerce.

As the development of national laws in Europe supplanted in large part the local and municipal laws and *coutumes*, they assumed the more general regulation of business. On the continent there has resulted a skeptical attitude toward "business ethics": unless the business act falls afoul either of the law or of sound economics, no further regulation seems necessary. In England, similarly, trade regulations were incorporated into parliamentary statutes or, as with the Law Merchant, were absorbed by the common law. Thus the basic business mores, such as good quality of materials, honest workmanship, sanctity of contracts, commercial arbitration and a strict sense of fiduciary relationships, although fundamentally sustained by public opinion, are

Business Ethics — Business, Government Services for 113

effectively sanctioned by law to a greater extent than in the United States, even though in England the doctrine of laissez faire has not yet been qualified by such measures as the Sherman Anti-Trust Act, the Federal Trade Commission Act and the Clayton Act.

It is in part as a reaction to such legal control of business that self-government and ethics in business have become dominant in American corporation and trade association policies. Centralized political control, so characteristic of western civilization during the past few centuries, is giving way to a pluralistic functional autonomy of business groups. This situation has been intensified by the fact that economics has maintained such an abstruse and abstract character as to afford little guidance for the more intricate problems of business behavior; hence the empirical nature of business ethics. The inevitable tendency to become absorbed in law or economics may eventually leave no residuum of business ethics, strictly so called, but at present the field is teeming with rich material.

Methodologically, business ethics is still in a formative state. The "code" stage is definitely a matter of the past, having been superseded by the "trade practise submittal" and the formulation of corporation policies. The latter, however, in spite of their empirical foundation, represent but the beginning of an adequate method of study and control. Business decisions, although devoid of the sanctions vested in the courts and therefore not amenable to the rule of *stare decisis*, are cumulative in that they contribute to the development of certain empirical generalizations as to business policy. Indeed the changing conditions to which business life is constantly subject would make inexpedient as rigid a system of precedent as prevails in the law. The most subtle problem of business ethics consists in discovering the sanctions which prevail in business activities and which therefore must be relied upon in order to effect the appropriate measure of control over business conduct. Whether this control will be relatively extrinsic or intrinsic rests in large part with business men themselves.

BUSINESS, GOVERNMENT SERVICES FOR. The concept of the proper relation between business and government has varied with changes in the economic and political fabric of society. The typical economist, political scientist or practical business man of the nineteenth century, influenced by classical economic theory, by the obvious inadequacies and hindrances of mercantilist regulations and by the rapid growth of industry and commerce under unrestricted free enterprise, was convinced that a minimum of state interference was the normal, good course. In fact, however, the span of bona fide laissez faire as an actual policy has been relatively brief. Government has always been concerned with business, although the reasons therefor have varied widely in different ages.

Elaborate regulation of industry and trade by the town councils is a well known aspect of life in the Middle Ages. But the purpose of the strict requirements was service to the consumer rather than to industry as such. The quality of workmanship and of materials was subjected to scrutiny in order to protect the purchaser. While it is true that in some of the town fairs the rules favored local merchants and handicapped foreigners it is fair to say that industry had no significant service from governing bodies during the Middle Ages. With the growth of national states and the beginnings of capitalism the promotion of industry and trade came to be a prime concern of governments. The emphasis, however, was not upon industry but upon the state. The mercantilist doctrines of regulation of production and control of trade, which flourished in the sixteenth, seventeenth and early eighteenth centuries, were based upon faith in gold and a favorable balance of trade as the means to pro-

mote strong national states. Colonial expansion became desirable as a means to secure markets. Great trading companies such as the Dutch West India Company and the (British) East India Company were given enormous land grants and were supported by their governments in matters of direct or indirect territorial aggression. Such activities were regarded as directly contributing to the welfare of the state. Cameralism even more narrowly than mercantilism regarded revenue to the prince (which term was practically synonymous with the state) as the chief aim of economic activity.

The *laissez faire* reaction of the eighteenth century was based upon a changed concept of national wealth; national riches were no longer identified with riches of the sovereign but with those of the people. With the rise of the bourgeoisie to control of government increase of the national wealth in its new sense became a chief interest of government. The newly acquired power of the industrial classes was used to remove the outworn system of restrictions and regulations and to give business enterprise a free hand. The new philosophy was that the greater the prosperity of the people, the greater would be the prosperity of the state and that the means to both of these happy ends was to unfetter business. The repeal of the corn laws, abolition of bounties on exports, lowering and repeal of tariffs, were manifestations of bourgeois use of political power to secure freedom for business activity, a movement which reached its peak in the twenty years from 1850 to 1870.

After the Franco-Prussian War the spirit of liberalism waned and it came to be believed that the problem of finding markets for the ever growing output of the factories was of increasing magnitude. The bourgeoisie then began to clamor for government assistance and there emerged a new interpretation of the relation between business and government. Business, once regarded desirable principally as a producer of taxable income, gained in relative importance until today commerce is, according to Chamberlain, "the greatest of political interests." The aggressively nationalistic attitude of the later nineteenth century resulted in closer union between business and government as partners in the world struggle.

It was in this spirit that the most conspicuous government services for business were developed. Business received assistance most readily in those phases which were directly affected by international competition. To assist merchants

to outsell the foreigner became the primary aim of the governmental departments devoted to the commercial interests of the state. It is not surprising then that the first important examples of specific government aid to industry occur in connection with foreign trade and that from such nuclei has developed a vast network of governmental bureaus, departments and offices whose primary function is the promotion of trade and industry.

Departments or ministries of commerce have been established in practically all industrial and commercial countries. Although their structure and relationship to other governmental departments vary from country to country they engage in similar activities. Virtually every country has a system for maintaining officers in residence abroad who report to a central office at home regarding such details of business conditions as prices, marketing possibilities for specific commodities, tariff and customs policies and harbor and inland transportation facilities in the localities in which they are domiciled. Prior to the nineteenth century fragments of such information came from business men without special training already residing abroad, who were appointed as consuls, and by 1832 there had developed a universal system of trained consular service. The consuls do not represent the state as a political body but are business or commercial agents. Their duties are prescribed by the state which sends them but may be limited by the state which receives them, usually on the basis of already existing consular treaties. Within recent years the consuls have been supplemented by commercial attachés, trade commissioners and other special agents who are particularly effective in securing information regarding trade possibilities. Every possible publicity is given to such information. It is published and circularized in reports and bulletins of the respective ministries or departments. In many countries main and branch consulting offices are maintained where the material can be secured first hand. The foreign agents of the government when home on leave are available at these offices for consultation with business men. Exporters and merchants are invited to enter their names upon private lists which are circularized with material of a specific nature as it becomes available.

The French Ministère du Commerce et de l'Industrie, which assumed its present form in 1886, is an outgrowth of one of the earliest examples of official recognition of needs of

trade. Although a separate ministry to look after the needs of commerce was not created till 1831 its origin dates back to 1588 when all commercial matters were placed under the supervision of Martin Ruze, Seigneur de Beaulieu.

The Office National du Commerce Extérieur, founded in 1898 through the cooperation of the Chambre de Commerce de Paris with the Ministère du Commerce et de l'Industrie, is the distributor of trade information relating both to the foreign and to the domestic market. This Office National maintains fourteen branch offices in France. Commercial attachés and commercial agents under the supervision of the minister of commerce are stationed in foreign countries. In the instructions issued to them the commercial attachés are defined as primarily advisers of the ambassadors and consuls. They must keep the Ministère du Commerce informed of important commercial events and supervise the various trade promoting activities of the government in their territory.

Coordination is brought about largely through the Office National, which is administered by a director assisted by a council of nineteen members variously appointed by the Chambre des Députés, the president of the Chambre de Commerce de Paris, the Assemblée des Présidents des Chambres de Commerce and the minister of commerce.

Great Britain has no actual ministry of commerce. The functions which might be fulfilled by such a ministry are distributed among various departments of state but are chiefly brought under the care of the Board of Trade. It is commonly accepted that the germ of this body may be found in the special committee of the King's Privy Council, which was directed in 1621 "to take into their consideration the true causes of the decay of trade and scarcity of coyns within the Kingdom and to consult of the means for removing of these inconveniences." Under Cromwell a Committee and Standing Council for the Advance and Regulation of the Trade and Navigation of the Commonwealth, composed of more than seventy members and appointed in 1655, gave this committee more permanent form. This council, dissolved in 1674, was reborn in different form under William III and entrusted with the administration of the "plantations." It passed through a period of great prominence from 1747 to 1761 under the leadership of the Earl of Halifax. Declining in importance it was abolished by Parliament in 1782 only to be reestablished with

enlarged powers by William Pitt by order in council on August 23, 1786. This order still forms the fundamental instrument from which the Board of Trade derives its general authority. In its early years the board performed largely advisory functions but in later years has become more of an administrative body.

Interimperial coordination of trade promotion in the British Empire has been accomplished by means of trade commissioners appointed by the Board of Trade serving as representatives in the dominions and dominion representatives serving in various other dominions, all making their services reciprocally available. The Department of Overseas Trade, created in 1917 and jointly responsible to the Foreign Office and the Board of Trade, coordinates all the trade promoting activities of the British government. A new Commercial Diplomatic Service, whose highest grade officers are known as commercial counselors, was created to replace the commercial attaché system of trade investigations in foreign countries. In fact, although the preparation of commercial treaties and other agreements with foreign governments is left with the Board of Trade, this function is assigned to a special department, the Commercial Relations and Treaties Department organized in 1919.

In Germany, similar governmental organizations had been created in the several states before the beginning of the centralization movement which found its culmination in the German Empire. When in 1810 the Prussian state was reorganized and ministries established, the interests of commerce were entrusted to the Ministry of the Interior. In 1848 a separate Ministry for Commerce, Industry and Public Works was formed. In addition to this administrative department an advisory body, the Volkswirtschaftsrat, was created in 1880 with seventy-five members chosen by the king, the chamber of commerce and agricultural associations. In the imperial government a Department of Commercial Policy was established in the Ministry for Foreign Affairs (Auswärtiges Amt) and a Commercial Division was organized in the Department of the Interior. The distribution of trade information takes place through a central office for foreign economic information (Zentralstelle für den wirtschaftlichen Auslands Nachrichten Dienst). This office is maintained jointly by the Department of Foreign Affairs (Auswärtiges Amt) and the Ministry of Commerce (Reichswirtschaftsministerium). The field work is in the hands of the consuls under the super-

vision of the Aussenhandelsstelle established in the Ministry for Foreign Affairs. In some cases vice consuls or secretaries of legations are designated to undertake commercial investigation and reporting work. Before the war a commercial attaché service existed but this has now been discontinued.

In the United States the act of February 14, 1903, created a Department of Commerce and Labor, to promote the mining, manufacturing, shipping and fishing industries and the transportation facilities of the United States. Functions developed first in other departments such as the Bureau of Statistics, the Census Office, the Bureau of Labor and the Bureau of Foreign Commerce were brought together to form the new department. By the act of March 13, 1913, the Department of Commerce and Labor was divided into two departments and the newly created Bureau of Foreign and Domestic Commerce became a part of the new Department of Commerce. Although the new department is to some extent an administrative agency its more important functions are concerned with promotion of the nation's industry and trade. It is now comprised of the Aeronautics Branch, Bureau of the Census, Bureau of Foreign and Domestic Commerce, Bureau of Standards, Bureau of Mines, Bureau of Fisheries, Bureau of Lighthouses, Coast and Geodetic Survey, Bureau of Navigation, Steamboat Inspection Service, United States Patent Office and the Radio Division.

The department has been active in promotion of foreign trade. Commercial information supplied by consuls, formerly published by bureaus within the Department of State, has since 1912 been placed under the care of the Bureau of Foreign and Domestic Commerce and since 1915 has been published as the weekly *Commerce Reports*. The Department of Commerce has also inaugurated its own trade information service. Four "special agents" were appointed in 1905 by the secretary of commerce and labor and placed under the direction of the Bureau of Manufactures; one was assigned to Cuba, Mexico and Canada, one to South America and two to China and Japan. In 1914 this service was greatly expanded. Provision was made for commercial attachés, appointed by the secretary of commerce but accredited through the Department of State, who report upon conditions in trade and industry abroad which may be of interest to the business men of the United States. They are assisted by trade commissioners and assistant trade commissioners. These officers perform

valuable service in assisting in the settlement of trade disputes and in advising American firms in regard to the methods of overcoming the difficulties of foreign customs and trade regulations. When on leave of absence from their foreign posts trade commissioners and commercial attachés visit district offices established in various American cities, where conferences with local exporters are arranged for them. In order to expedite still further the transmission of trade information to exporters the bureau maintains a list of American firms interested in foreign markets. The firms whose names appear on this exporters' index receive confidential information regarding trade opportunities and receive the benefit of other services "that cannot very well be arranged for in any other way."

Through this expansion of the Bureau of Foreign and Domestic Commerce a new foreign service has been built up which in a sense parallels the consular service. A method has been devised, however, by which the Department of State provides contact between the consuls in the foreign field and the Department of Commerce. Furthermore it is argued that consuls, burdened with routine of their offices and tied to one place, are in no position to serve efficiently as sources of trade information.

The Department of State has several times attempted to create a service less confined to administrative duties. After the disbanding of the Bureau of Trade Relations the office of Foreign Trade Adviser was created. During and immediately after the war the department was in urgent need of expert economic and trade advice in order to be guided in its dealings with foreign problems and in the drawing up of commercial treaties. In 1920 a personnel of almost seventy employees had been built up for this service. The possibility of using this organization for the collection and distribution of information useful to the business interests now became apparent, and consequently the consuls were encouraged to extend their activities along the lines of commercial investigations. By executive order on November 18, 1920, the consular regulations were amended to provide for the designation of a number of consuls as "economic consuls" to serve as assistants to general consuls in economic investigational work. The duties of these newly created officials were almost identical with those of the commercial attachés. This expansion was short lived, for in 1921 the activities of the Office of the Foreign Trade Adviser in the promotion of commerce ended

The Department of State continues to devote increasing attention to the collecting of trade information, on the principle that diplomatic relations can no longer be considered apart from economic relations.

Attempts to promote trade have not been limited to the confines of single countries. The League of Nations has done some valuable work in promoting "equitable treatment of commerce" among League members. It has appointed committees to examine various practices which clearly violate the principle of equitable treatment. Studies have been made of unfair competition, treatment of foreign nationals and enterprises, customs formalities, import and export prohibitions and restrictions, commercial arbitration and legislation on bills and checks. Recommendations have been put forward for uniformity in statistical methodology with respect to international trade, agricultural production, fisheries, censuses of production and current industrial production. A permanent subcommittee has been formed to consider economic crises and unemployment. The Organization for Communications and Transit holds general conferences at regular intervals to secure and maintain freedom of communications and transit. Between conferences the work is carried on by an Advisory and Technical Committee for Communication and Transit, which is a governmental organization with membership made up of states permanently represented on the council and states selected for the purpose. Its chief work is directed toward mitigating administrative formalities and technical difficulties obstructing easy and rapid transit between nations.

The United States is a party to a number of international agreements formed prior to the appearance of the League of Nations for the promotion of international trading interests. The Inter-American High Commission, organized in 1915 under the auspices of the First Pan-American Financial Conference, aims among other things at uniformity of commercial law and stability of financial relations between the Latin American republics and the United States. The International Hydrographic Bureau, formed in London in July, 1919, on the recommendation of delegates from twenty-two nations, seeks to promote hydrographic research and thus to facilitate navigation. The International Bureau for the Publication of Customs Tariffs was created in Brussels July 5, 1890, and the International Statistical Institute in London June 24, 1885.

The termination of the World War witnessed renewed activity on the part of governments to assist business to survive the difficulties of readjustment. One of the post-war developments was the application of various methods of assisting exporters in financing their exports. Great Britain inaugurated a credit insurance plan in 1920 and established an Export Credits Office in the Board of Trade for its administration.

The German export credit insurance plan was inaugurated in 1926. The plan, worked out under the Reichswirtschaftsministerium, placed the actual insurance in the care of two designated insurance companies which carry two thirds of the risk. The government agreed to indemnify the companies for one half the amount they would lose on "normal" risks. A similar export credit insurance plan was established in Holland in 1923, in which a risk of 40 percent of the invoice value was assumed by the government.

The bonus or bounty offered to exporters is another method which has been increasingly used in recent years to encourage exports in selected products. Australia has paid a bounty on butter since 1928, Latvia on flax, Spain on rice and certain cotton fabrics. Such measures may lead to international economic friction and are therefore resorted to in comparatively few instances.

In the United States the Federal Trade Commission was charged with the administration of the Webb-Pomerene Act of 1918; this act allows American firms which are not permitted to combine in the home market to pool their efforts when dealing with foreign markets.

From the days of Colbert great powers have been solicitous of the merchant marine, partially because of a belief that it promoted trade in general but particularly because of its military significance. Modern governments promote national shipping by loans at low rates of interest, by guaranty of loans from private sources, by assumption of part of the interest charges, by subsidies or subventions to individual shipping companies, by preferential rates on the railroads to exports carried on national steamship lines, by imposition of higher tariff rates on goods imported or exported in foreign ships, by visaging without charge passports of persons traveling on national ships and by granting particularly profitable mail contracts to ships flying the national flag. Great Britain, France, Sweden, Spain, Italy, Japan, Brazil, Chile, Portugal and the United States all make use of one or more of these mechanisms.

A consequence of the extreme rivalry for markets and of the promotion of foreign trade characteristic of the mercantilism of the fifteenth to the eighteenth century, as well as of the later nineteenth and early twentieth centuries, was the development of a certain amount of regulation of domestic industry. One means of insuring a foreign market for goods was to make sure of their superior quality. This latter result supposedly could be achieved by minute regulation, the policy attempted by Colbert, or by various forms of government branding or certification of quality after inspection, a policy employed today.

As early as 1904 the government of Holland originated a governmental certification service for butter exported from that country. The rapid decline of the butter trade with England on account of the failure of the Dutch exporter to maintain quality had led to this attempt at standardizing the quality of the exported product.

In recent years many similar inspection and certification services have been organized in other countries. Inspection of tobacco intended for export takes place in many countries. Mauritius maintains special governmental warehouses where the product is graded and prepared for export. No exports can take place except on government certificate. The Philippine Bureau of Agriculture not only grades and inspects the tobacco but in order to promote the growing of better grades has power to control the planting as well as the methods of cultivating and curing. Of special importance is the inspection, conditioning and certification of silk intended for export by the government of Japan and by the city of Kobe. This service has contributed measurably to increase the prestige of Japanese silk on the world's markets.

Exports of meat from Argentina can take place only if accompanied by an official certificate and if packed to conform with governmental standards. Herring exported from Holland, bananas and tomatoes from the Canary Islands, fresh fruit from Canada, eggs in pulp or in shell from Australia, butter from New Zealand and Ireland, meat products from Estonia, oranges and castile soap from Spain, are subject to similar inspection.

In some cases goods which have successfully passed inspection are given the exclusive privilege of carrying the national trademark. Thus the Italian government inaugurated in 1928 a national trade mark the use of which is granted to approved firms and inspected products. The

Persian government maintains a Belgian expert to examine Persian rugs for the detection of the use of any aniline dyes. The British government guarantees the quality of barrels of herrings cured in Scotland by marking them with the crown brand. Such certification of quality of merchandise which is the chief product of, or is obtainable in, only one country is important in maintaining confidence in values.

Although government service for business started chiefly in connection with foreign trade, governments have of late years given much attention to the promotion of domestic industry. Governmental bureaus and departments similar to those engaged in promoting foreign trade are designed to encourage home industry. Tariffs of most great powers have been substantially raised since the 1870's. Industries important for national self-sufficiency, or frequently simply those powerful enough to exert sufficient pressure upon governments, have been specially favored. With the increased variety of industrial products and the increased complexity of business organization there has also arisen a demand for government standardization and experimentation. Direct government assistance has been granted to those types of industry which could not exist within the nation except for such aid.

The Bureau of Foreign and Domestic Commerce in the early years of its existence was unable to engage upon any important program of domestic trade promotion because of the absence of funds. The act creating the bureau had charged it with the making of comparative studies of the cost of production of certain articles abroad and in the United States, but it was not until the fall of 1913 that funds became available for this purpose. During the next four years about a dozen reports were published on different American industries; in 1917 this important work was transferred to the newly created Tariff Commission. The division of cost accounting, organized in 1917 and intended to serve the business world through the collecting of uniform cost data which could serve as a guide in production, was closed in 1918 when this work was transferred to the Federal Trade Commission. Isolated studies of domestic industries and trade associations were made from time to time but the domestic side of the bureau's work was not of very much importance until the organization of the Division of Domestic Commerce in 1923. This year was the beginning of the bureau's domestic activities on a large scale.

One of the most important and constructive

pieces of work of this new division was the organization of regional surveys, the first of which to be completed was the *Commercial Survey of the Southeast*, published in 1927. Similar surveys have been made of other sections of the country. Each survey deals with merchandising methods, commodity preferences, buying habits, store and plant location and the machinery of distribution of the area studied.

The most recent development is the making of cost of distribution studies. These studies are carried on with the cooperation of individual firms and various trade associations. Little is known at present of the various factors influencing the cost of distribution of commodities and important results may be expected from these systematic cost studies. The division is further active in cooperating with trade associations in the making of commodity marketing surveys especially where the trade is not sufficiently well organized to carry on such investigations on its own initiative.

A special section to serve the interests of the small business man has recently been organized. There is a special inquiry section to serve as a clearing house for business information and to acquaint the business world with the many government bureaus from which they may obtain information.

Besides the Department of Commerce many other government bureaus are engaged in studies of domestic production and distribution methods. The Tariff Commission, organized to provide the government with the necessary data to furnish a sound basis for a tariff policy, carries on studies at home and abroad in order to arrive at comparative costs of production. Its publications dealing with foreign tariffs, commercial treaties and certain domestic and foreign industries form valuable contributions to the field of commercial knowledge. The Federal Trade Commission is another agency which, although organized to control rather than to promote commerce, has produced studies of very great use to business. The published reports dealing with the grain trade, the copper market and a large number of industries contain valuable material for the business man. Of particular interest are the studies dealing with trade associations and with the standardization of trade practices and trade terms. The commission by investigation and recommendation in cases of charges of illegal conduct has performed valuable service in the settling of trade disputes and in eliminating unfair practices.

The Bureau of Standards, organized in the Department of Commerce in 1901 and originally intended to operate largely as a custodian of standards of weights and measures, has expanded its activities until today hardly an industry remains unaffected by its manifold contributions. Its scientific research and testing of materials have resulted in important improvements in engineering and manufacturing technique. From the point of view of the merchant the bureau's activities along the lines of simplified practise and the standardization of products are of the greatest significance. The acceptance of such simplified practise and standardized production by many of the trades has resulted in substantial savings in inventories and production costs and has made for a reduction of charges for obsolescence of machines. Standardization also has contributed greatly in eliminating causes for trade disputes.

Among the industries which could scarcely exist without government aid are fisheries and air transport. In the United States the Bureau of Fisheries engages extensively in the planting of fish in waters suited to their propagation and regulates the fishing seasons to prevent their extermination. It also sends government experts to fishing centers, where they advise and check upon fishing activities.

Aeronautics has been assisted by direct subsidy to commercial air transport, by government research, by development of standard air practises and by circulation of information. Air transport, while it has had a tremendous recent growth, cannot yet be counted upon to operate commercially without artificial financial assistance. In Europe direct subsidies and air mail payments are made to the national monopolistic transport companies. In the United States air mail contracts, provision of lighted airways and information service by the Aeronautics Branch of the Department of Commerce serve to promote commercial transport. Earlier in American history the railroad land grants served the same purpose.

Other industries have the research and advisory services of special bureaus of the government. In addition to the Bureau of Standards, the Bureau of Fisheries and the Aeronautics Branch the Department of Commerce maintains the Bureau of Mines to assist the mining industry to eliminate waste and safeguard lives, the Radio Division to promote and regulate the radio industry and the Chemical Division of the Bureau of Standards, which makes available the

results of its researches to those industries which might benefit thereby; while the Department of Agriculture maintains the Bureau of Plant Industry, Bureau of Animal Industry and Bureau of Dairy Industry.

Government solicitude for business is particularly marked when the economic fortunes of the nation are determined by the welfare of a single industry. The world's chief sources of coffee, sugar and rubber are Brazil, Cuba and the British East Indies respectively. In the decade following the World War the British and Cuban governments engaged in heroic attempts to stabilize the prices of rubber and sugar by the control of supplies going upon the world market. But the ultimate effect of these means an increase in production in other economic areas and both of these valorization schemes have been abandoned. Beginning in 1906 the governments of the Brazilian nation and of the state of São Paulo, at first intermittently but more recently continuously, have participated in the marketing of coffee. Here again price regulation has been attempted through artificial control of supplies moving into the market and although it has not yet been proved a failure it is seriously embarrassed by the failure to restrict the amount of coffee produced.

From 1879 until the retrocession of Alsace Lorraine to France in 1919 the German potash syndicate was sponsored by the Prussian and the German governments, which restricted output and allocated quotas to the various mines; in 1924 an agreement was reached between France and Germany whereby the two countries in combination exercised a similar control of the output of potash. Government officials have participated in the management of the syndicate, prices have been restricted, production has been forcibly curtailed and foreign prices have been forced far above the domestic. All these measures have been undertaken primarily for the enhancement of the profits of the owners and secondarily in the interests of cheap fertilizer for agriculture.

Since 1891 Canada has progressively developed a policy of restriction of export of pulpwood and even of pulp. The primary motive has not been conservation but the promotion of domestic industry. By the restriction of pulpwood exports the pulp mills of Canada are benefited, while the restriction of pulp exports stimulates the developing paper industry of the country. These restrictions appear to have been of genuine benefit to Canadian industry.

As a result of legislation passed by Great Britain in 1903, 1904 and 1916 a prohibitive tax has been placed upon export of tin from the Federated Malay States and Nigeria unless it is destined for smelting in the Straits Settlements, United Kingdom or Australia. From 1902 to 1913 the United States levied a similar tax upon manila exports from the Philippine Islands except those consigned direct to the United States. The British tax has effectively restricted foreign competition in smelting, but the manila tax, repealed in 1913, had little effect other than to eliminate indirect shipments to the United States via Great Britain.

Still other forms of financial assistance to domestic industry, direct and indirect, have appeared since the war. The British Trade Facilities Act of 1921 established a fund intended to facilitate the financing of power plants, harbors, dock works and railway equipment in England and abroad by means of long term loans. The loans were restricted to enterprises which give employment directly or indirectly to British labor. The miners of wolfram and tin in Burma are able to secure loans from the local banks more readily because the government guarantees the credit. Spain and Portugal give financial support to the coal industry and Poland, Belgium, France, Canada and South Africa assist this industry by means of preferential rates on their railroads. South Africa subsidizes its infant steel industry while Japan, under the Steel Manufacturing Industry Encouragement Bill, provides for tax exemption for a period of fifteen years for plants equipped to produce a minimum of 35,000 tons of steel per annum. The Japanese dye industry is similarly assisted, while under the law of 1925 subsidies are also provided for.

Canada has followed this example by granting a subsidy for fifteen years to encourage the establishing of coking plants. More thoroughgoing is the attempt on the part of the Turkish government to bring about industrialization of the country. Selected industries may procure exemption from customs and excise duties on goods imported to be improved in Turkish industrial establishments. Subsidies may be granted to such industries and the national and local governments may be required to purchase the products even at a price 10 percent above the price of imported goods. Tax exemption is frequently found and is a part of the method used by the Brazilian state, Amazonas, to foster new industries.

Compulsory patronage of home industry by central and local governments is another favored method of industrial promotion. Hungary by the ruling of May, 1926, Japan under the decree of March, 1927, and Portugal under a decree of the same year all use this method, while the government of India purchases only railway wagons manufactured within the colony.

One of the most consistently worked out plans for governmental assistance to industry is probably contained in the Spanish royal decree of April 30, 1924; the conditions are indicated under which an industry may become "nationalized" and thus obtain tax exemption, export subsidies, a guaranteed income and, if needed, a state loan as circumstances require.

International as well as national measures have been taken to promote domestic trade. In addition to the work of the League of Nations on standardization there are various international agreements. The North Pacific Halibut Act of June 7, 1924, gave effect to a convention signed March 2, 1923, between the United States and Great Britain for the preservation of the halibut industry. An International Fisheries Commission, composed of representatives of the two governments, is to determine the necessary scientific investigations and practical policies. In 1875 the United States became a member of the International Bureau of Weights and Measures, which maintains standards of measurements and keeps instruments in Paris of which those of the United States Bureau of Standards are copies. The Union for the Protection of Industrial Properties, concluded in Paris in 1883, was proclaimed in 1887, with a revised convention proclaimed in the United States in 1913. It is constituted to protect citizens and subjects of member countries with respect to patents, trademarks and commercial names. The International Trade-mark Registration Bureau, created by convention at the Fourth Pan-American Conference of American States in Buenos Aires in 1910, provides for trademark registration bureaus for pan-American countries.

Government service has also been effective in problems of management and adjustment of labor. The United States Division of Conciliation, although it has not exerted a wide influence, renders a distinct service in so far as its friendly advances may prevent stoppages and the attendant loss to both employers and labor. Public employment exchanges, now universal in England and most of Europe and maintained in the United States by some states and municipi-

palities, are valuable in expediting the hiring of labor and improving the choice of labor. In 1928 a draft convention favoring a uniform system of free public employment agencies was drawn up and has been signed by twenty-three countries but not by the United States.

Technical education has been carried to a very high point by the German government and has resulted in important contributions to industry by trained chemists and engineers. Other continental countries are following the German lead. In America vocational education is receiving increasing attention in state and local systems, and the United States government maintains a Bureau of Vocational Education.

Among the government activities which particularly facilitate domestic trade as a whole are the building or improving of canals, harbors, highways and turnpikes. Germany is outstanding in its highly organized governmental provision for interior transportation and harbor facilities and promotion of transportation by rail. Municipal, state and national governments have worked in close cooperation to provide excellent and cheap transportation, the expenses of upkeep being paid out of general taxation. The railways have favored certain German seaports to enable them to compete with the ports of Holland. In the United States and England there are many municipally owned docks and terminal facilities provided for public use.

Many cities maintain municipal markets where at little expense and under favorable conditions vendors of produce may meet prospective buyers. The adoption of city planning and the enactment of zoning laws in cities benefit local industry in general by concentrating the commercial areas and thus facilitating transactions and transportation. Where public needs call for coordination of government regulations over a wider area than a municipality there has arisen a new type of government authority, one based on an economic area, as for instance the Port of New York Authority and the Sanitary District of Chicago.

A movement which has been of distinct service to business is the attempt to bring uniformity into certain state laws relating to industrial practices. The National Conference of Commissioners on Uniform State Laws was formed in 1892 by representatives of twenty-nine states and now comprises commissioners from every state, the District of Columbia, Alaska, Hawaii, Porto Rico and the Philippine Islands. After careful study of the best practice and of all

existing state legislation it has prepared model acts, including a uniform sales act, stock transfer act, negotiable instruments act, warehouse receipts act, bills of lading act, conditional sales act and aeronautics act. These model acts have been passed verbatim or with very little change by many of the states and hence have helped to simplify interstate commerce. The Conference of Commissioners on Uniformity of Legislation in Canada, organized in 1918, is composed of commissioners from each of the nine provinces, appointed under authority of provincial statutes. It has drawn up and secured adoption by several provinces of such bills as a uniform bulk sales act, warehousemen's lien act, conditional sales act and bills of sale act.

It still remains true that the greater part of the government services for business are concerned with foreign trade. The prime objective is the promotion of exports largely through the provision of elaborate information concerning opportunities for nationals to sell abroad. Little or no complementary attention is given to the provision of information concerning opportunities for nationals to buy abroad advantageously. Implicitly underlying this concern for exports is the same philosophy which defends the protective tariff. With one hand the government erects tariff barriers to impede importation while with the other it appropriates vast sums to facilitate exportation. Both hands are engaged in the promotion of a favorable balance of trade.

Next in importance to those services which promote a favorable balance of trade are those designed to insure military strength. The active promotion of commercial aviation, the solicitude of great powers for the national merchant marine, the attention lavished upon the explosives industry and during the last quarter century the dye industry are examples of government service to business with an ulterior military motive. Many great public works which are a boon to business are likewise of great military importance. As an example the construction of the Panama Canal was an inevitable response to this joint demand.

A few of the government services for business are, however, of a type which unquestionably increases the national dividend. They are generally services which cannot be effectively performed by private persons. Many do not represent a trend away from *laissez faire* but are adjustments which permit its perpetuation in the essential particulars. Employment exchanges permit mobility of labor; statistical services aid the

realization of the long hypothesized universal knowledge of the perfect market; roads, harbors, canals, money and banks contribute to that fluidity which prevents price disparity.

Nevertheless, with some possible exceptions, the prevailing concept of the function of government is essentially a return to the philosophy of mercantilism. If the business man cannot compete successfully alone in world markets it is held that the government should intervene. Such is the accepted doctrine. There exists a widespread faith in the ability of the government to remedy any ills of business which it chooses to attack.

BUSINESS TAXES, in the widest sense of the term, may be distinguished from other levies such as general property taxes and general income taxes by the fact that they are collected from the business man as such, and depend directly upon the flow of business. The general category includes customs duties, stamp taxes on commercial bills, checks, transportation documents, taxes on stock and produce exchange transactions, general sales taxes, special commodity taxes collected upon production, sale or transportation, corporation taxes and perhaps even those sections of the general income taxes which apply to business profits. In this article, however, the term will be considered in its narrow sense, as referring primarily to such taxes as the French *patente* and German *Gewerbesteuer*. In this sense a business tax is one levied upon practically all business firms, and

likewise without regard to the personal status of the natural persons connected with the business. Even from this point of view the general sales or turnover tax is one form of business taxation, and much of what is said here applies to it as well as to such a tax as the *patente*.

The business tax is to be found chiefly in continental Europe. It does not exist in England. In the United States the federal tax on corporate net income is a step toward the business tax, and some of the states, those of the South especially, show in their systems of license, occupation or privilege taxes an approach to a general business tax. State corporation taxes exhibit many of the characteristics of a general business tax, especially when accompanied by a tax levied on unincorporated concerns, as in Connecticut—even though the bases of the two taxes differ. In France the *patente*, once a mainstay of national revenue, has since 1917 been restricted to the use of the *départements* and communes. The national government employs, among other types of income tax, a levy on business profits whether received by corporate or by non-corporate enterprises. In Germany the federal government has no general business tax, but the *Gewerbesteuer* of the states and localities is in many instances patterned closely after the *patente*, and in any case may be considered a business tax in the sense employed here. The *patente* has likewise served as a pattern for the general business taxes of Spain, Portugal, Soviet Russia, Poland and Japan.

Various methods may be used for calculating the tax due. Indeed, one of the striking characteristics of the business tax is that the measures employed for different firms may differ, and a given firm may be taxed upon several different bases. The measures used include type of business, population of the locality in which the business is carried on, rental value of business premises (and even of the dwellings of the business owners), amount of floor space in business premises, gross sales, total amount and unit sizes of machinery and equipment employed, number of workers, size of payroll and amount of capital employed. This variety indicates both an unwillingness to probe deeply into the possible economic effects of the tax and a desire to levy as much as possible by easily ascertainable "external signs." The same may be said, however, of many of the simpler occupation taxes of the southern United States, which are often flat taxes on the individual engaged in the business, varying not at all with the size of the enterprise.

The modern tendency in Europe, nevertheless, is toward a closer attention to net income as the measure of taxable capacity. In the French schedular tax on business profits levied for the national government an effort is made to smooth out some of the grosser inequalities in the burdens laid upon various business owners. But even the most refined use of the net income measure falls short of the test of relative ability as among individual owners, because of the failure to consider other elements which make up the owner's economic status, including family burdens, income and losses from other sources, etc.

General business taxes have been defended on various grounds, one of the soundest of these being ease of collection. Business income is concentrated in relatively few hands and is not so readily concealed as many items in personal income. Moreover some part of business income, when distributed among its ultimate beneficiaries, finds its way beyond the jurisdiction of the taxing body. Especially in states or subdivisions of states which draw much of their business capital from without, the argument for business taxes appears compelling. It is urged that businesses enjoying the protection of a state should pay for it through taxation. This argument involves obviously the benefit theory of taxation, which here as elsewhere suffers from the difficulties encountered in attempts to trace and allocate benefits. Consumers as well as producers benefit from business; whether the burden will be shared fairly by both classes depends upon questions of incidence to which the defenders of the tax have given little consideration.

Some attempts have been made to defend the general business tax on grounds of ability to pay. But the faculty theory is essentially applicable only to individuals. If two firms have the same gross receipts, the same amount and structure of capital investment and the same net income, there is yet unequal "ability to pay" if one is solely owned by a natural person who has a large income from other sources and no family burdens, while the other is owned by many comparatively poor people. All that the faculty principle can mean as applied to the business firm as such is that it can pay the tax without being forced out of business or without being hindered too much in efforts to raise new capital. In any event the tax departs from the conventional canon that each citizen should contribute to the state according to his

economic position as a whole. Such a departure may be best understood in the light of the breakdown of existing taxes, such as the general property tax, and of the general uncertainty as to the precise economic effects of many taxes.

It may be argued that the levy of a general business tax is indicative of a vague, usually unexpressed intent on the part of the state to levy a permanent, capitalized rent-charge on the net profits of business firms in lieu of taxation proper. In many states of the United States, in fact if not in law, the real property section of the general property tax has become a tax *in rem* on land and improvements, the personal situation of the owner being entirely disregarded. This tax, at least so much of it as is levied on the land, may be capitalized. One who purchases after the tax is levied takes the future annual charges of the tax into consideration when setting his offering price and is little or no worse off than he would have been had no such tax been levied. Might not a similar situation develop through taxation of going business concerns? It might, if there existed somewhere a relatively tax-free field for investments and if the tax could not be shifted to the consumer. The latter point involves the allowance of imputed interest on ownership capital as a deductible expense. The present federal income tax on corporations can probably be considered to some extent as a capitalized rent-charge.

Not all business taxes are so framed as to be readily capitalized. Much depends upon the degree to which the personal status of the owner is allowed to influence the amount of the tax levied. If, in the calculation of taxes due, allowance is made for the family status of the business owner, as is done in the national tax on business profits in France, accurate capitalization is impossible. The purchaser of a business is not certain as to what his future tax charges may be and the seller of a business knows that its selling value must depend to some extent upon the family status of the future purchaser. To a lesser degree the same difficulty exists in connection with the *patente*, to the extent that the amount of the tax paid is influenced by the rental value of the dwelling of the owner.

The future of business taxes in the United States appears to depend first upon relative ease of collection in comparison with other tax forms, especially the general property tax, and second, upon a willingness to introduce into the tax system an important levy which does not

attempt either to trace closely the benefits to individual natural persons or to measure accurately their ability to pay. Present conditions point to an extended use of business taxes, largely because of ease of administration. Corporate businesses are already taxed, and expediency suggests the imposition of a tax on unincorporated businesses, by the states, in lieu of the highly unsatisfactory personal property tax. Those countries in which a business tax is already firmly established face the necessity of deciding whether an attempt should be made to burden the business firms as such rather than the consumers, and of revamping arbitrary and obsolete methods of calculating the tax base.

BUSTĀNI, BUṬRUS AL-. *See* BUṬRUS AL-BUSTĀNI.

BUTLER, JOSEPHINE (1828-1906), English social reformer. With her husband she advocated educational opportunities for women and was the first president (1867-73) of the North of England Council for Promoting Higher Education for Women. Her first pamphlet, *The Education and Employment of Women*, appeared in 1868 in London, and in the following year she edited the book *Woman's Work and Woman's Culture* (London), by a group of distinguished contributors.

At this time she began her "abolitionist" crusade in behalf of the repeal of the contagious diseases acts (passed in 1864, 1866 and 1869), under which brothels were licensed and compulsory medical examination of prostitutes required. Her famous "Protest of the Ladies" on this subject in the London *Daily News* (1869) was signed by many distinguished women. Contending that these acts worked a grave injustice

to women of the most helpless class and at the same time failed as a public health measure she secured in 1870 a royal commission of investigation. There was no woman member, but Mrs. Butler was called as a witness and made a deep impression, the commission reporting in favor of a repeal of the acts. In 1871 she published *Sussum corda* (Liverpool) and *The Constitution Violated* (Edinburgh), which advanced most convincing arguments against the official licensing of immoral houses and the state regulation of prostitutes. During the seventies she published more than a score of related books and pamphlets. She believed that this system was also connected with the international white slave traffic and carried on a vigorous controversy regarding the traffic between England and Belgium. In 1874 she opened correspondence with the opponents of the regulation system on the continent, and the next year took the lead in founding the International Abolitionist Federation with headquarters at Geneva. In England the Select Committee of the House of Commons to Inquire into the Operation of the Contagious Diseases Acts (1879-82) delayed action, but in 1883 the House of Commons finally passed a resolution condemning the "C. D. Acts," which were suspended and repealed in 1886.

Mrs. Butler also directed a demand for the amendment of the criminal law to secure greater protection for children and young girls. The Criminal Law Amendment Act was passed in 1885 with the somewhat spectacular assistance of W. T. Stead. During the last twenty years of her life she directed her efforts to the agitation for reform of conditions on the continent and to the situation in India. *A Doomed Iniquity* (London? 1896) was her authoritative condemnation of the state regulation of vice.

She was a very persuasive and convincing advocate of an equal moral standard for men and women; she also had great qualities of leadership; and her "repeal movement" remains a remarkable and successful example of public agitation in the field of social reform.

BUTLER, SAMUEL (1835-1902). English social critic, philosopher and novelist. Butler was born in a rectory at Langar, Nottinghamshire, where he passed his early years under pious parental bullying which produced a life long distaste for parents, parsons and churches. This found expression in his novel, *The Way of All Flesh* (ed. by R. A. Straatfeikk, London 1903), which he began in 1873 although he refrained from publishing it during his lifetime. It was one of the earliest and best of the now common enough novels of the misery of childhood and youth.

After a period at school and four years at Cambridge, during which he formed impressions of schoolmasters and dons no more flattering than those he had already acquired of fathers, mothers and rectors, he spent about five years on a sheep ranch in New Zealand and returned to England with his capital doubled. When in 1872 his *Erewhon* (a disguise for Nowhere) appeared anonymously, it was clear that he had found a way of discrediting the mores and institutions of his day by contrasting them with the by no means utopian scheme of life in Erewhon. Butler has been known as a satirist and a jester, one who in Joad's words "took the portentous lay figure of Victorian complacency by the throat and shook it until the stuffing came out." But he took his jesting very seriously and had always something of high import to make fun of. He refused, however, to be solemn, and so confused and irritated his contemporaries. As a commentator he was at his best in his *Notebooks* (a volume of selections has been compiled by H. F. Jones, 4th ed. New York 1926), in which he reported his day by day reactions to the serio-comic world in which he lived. Since his death Butler has come into his own. He can be easily understood and heartily relished by those who lived through the World War.

On his sheep ranch Butler had read Darwin's *Origin of Species* with admiration and then with increasing reservations and criticism. He was dissatisfied with Darwin's theory of accidental variations as the basis of natural selection and survival and accused Darwin of having wilfully neglected earlier researchers in the field of evolution. In 1877 Butler published *Life and Habit*, followed by three other books on the subject. He contended that the offspring was "identical" with the parents and unconsciously participated in their memories. Little attention was paid by the biologists of the time to his protests against the prevalent mechanistic theories, but in the

twentieth century Semon (in his *Mneme*) and Bergson made clear that the mechanistic assumptions were by no means self-evident or adequate. Butler was without knowledge of the strange discoveries being made just before his death in regard to inheritance and the nature of matter, but he said plainly enough: "We should endeavour to see the so-called inorganic as living in respect of the qualities it has in common with the organic, rather than the organic as non-living in respect of the qualities it has in common with the inorganic" (Joad, p. 76). The novel doctrine of "emergence" would have cheered his heart.

BUTRUS AL-BUSTĀNĪ (1819-93), leader of the modern Syro-Arabic national renaissance. Butrus was born in Lebanon, Syria, and studied at the Maronite college of 'Ayn Warāḥa. Converted to Protestantism by American Presbyterian missionaries he assisted them in organizing in 1846 a school at Abeih and later in making an Arabic translation of the Bible. He became interpreter at the American consulate in Beirut, settling there permanently in 1848. Butrus now devoted all his energies toward arousing the national consciousness of the Arabs, and through journalistic propaganda and educational activities helped more than anyone else to pave the way for the Arab national movement. In 1860 he founded the *Nafīr Sūriyya* (Syria's clarion) and in 1870 the *Al-Janān*, a political and scientific journal with the motto, "Love of fatherland is an article of faith." He founded a higher secular school in 1863 for the study of Arabic language and literature and six years later published a dictionary of the Arabic language. In 1875 he began the publication of his great Arabic encyclopaedia, by means of which he sought to popularize learning among the great masses of the Arab population. He himself completed only six volumes, although five more were published from his notes. Butrus

condemned the use of alcoholic beverages, defended the freedom of thought, sought to elevate the position of women and defended their rights to education. As teacher, linguist, translator and as founder and head of literary, ethical and religious societies his influence extended to all regions and classes of the Orient.

K. T. KHAIRALLAH

Consult: Khairallah, K. T., *La Syrie* (Paris 1912) p. 49-51.

BUTT, ISAAC (1813-79), Irish politician and economist. He studied at Trinity College, Dublin, where in 1836 he was appointed to the Whately chair of political economy. He was also a practising lawyer, being a member of the Irish and later of the English bar. Regarded at first as the rising hope of the Conservative party in Ireland Butt subsequently led the Home Rule movement and formulated the doctrine on which was based the program of the Irish Nationalist party. His plan called for a federal arrangement with England whereby an independent Irish parliament was to rule Ireland, while the English Parliament, including Irish representatives, retained its jurisdiction over national defense and foreign affairs. He was also a protagonist of the far reaching Irish land legislation of the latter part of the century. In this connection he published the *Practical Treatise on the New Law of Compensation to Tenants in Ireland* (Dublin 1871).

Butt's range as an economic thinker was limited and he did not pretend to originality. His ideas on the subject of value are borrowed from Nassau Senior and Say, while at other points he acknowledged his indebtedness to Longfield. He wrote also on a number of other subjects, among them the poor law for Ireland, sea fisheries and education.

W. H. DAWSON

Consult: MacNeill, J. G. Swift, "Isaac Butt, the Father of Home Rule" in *Fortnightly Review*, n.s., vol. xciv (1913) 448-59; Seligman, Edwin R. A., *Essays in Economics* (New York 1925) p. 118-19.

BUXTON, THOMAS FOWELL (1786-1845), English humanitarian and reformer. After his marriage in 1807 to Hannah Gurney, a sister of Mrs. Fry, the prison reformer, he lived at Spitalfields, where he took an active interest in the welfare of the working classes. In 1818 he entered the House of Commons as member for Weymouth and immediately attracted attention by his earnest advocacy of criminal law

reform. His *Inquiry, whether crime and misery are produced or prevented by our present system of prison discipline* (London 1818) resulted in the formation of the Prison Discipline Society.

In 1822 he became Wilberforce's active coadjutor in the antislavery crusade and three years later succeeded him as the recognized advocate of the cause in Parliament. In the final decade of struggle to build up an English public opinion in favor of emancipation Buxton made speeches, gathered and arranged statistics, marshaled evidence and directed the parliamentary tactics of his group. Defeated in his campaign for reelection to Parliament in 1837, he divided his time between prison reform and agitation for the abolition of the African slave trade. He founded a society for abolition in 1839 and wrote *The African Slave Trade* (London 1839) and *The Remedy* (London 1840). He also urged the naval expedition to the Niger, which was undertaken with a view to suppressing slavery by the introduction of agriculture and trade, but which ended disastrously.

BY-ELECTIONS. By-election is the term applied to a special election held in a single constituency in order to fill a vacancy in the legislature. Such vacancies may occur before the expiration of the term, when a member dies or resigns or is expelled by the assembly; sometimes an election may be declared void or a seat automatically vacated when a member accepts another office incompatible with membership in the assembly. At times the resignation of a member is engineered by a political party in order to make room for some person whose membership in the legislature is considered desirable. Generally the vacancy must be filled before the next general election to avoid the difficulty of leaving a constituency without the representation to which it is entitled. The methods of filling such vacancies differ. In many states of the United States the governor appoints congressmen or senators to hold their seats until the next election day. In a country like Germany with a "list" system of proportional representation, a member who drops out is succeeded by the next candidate on the same list. In this fashion representation is restored to electors

who have by accident lost a member. On the whole, special local elections are found practicable only in countries with small, single member constituencies. They are held at present in Great Britain, France and certain states of the United States. Because of certain features of parliamentary government and of the party system the by-elections in Great Britain are at times of major political significance.

A vacancy in the House of Commons may occur not only in such circumstances as have been described, but it may also be created in a manner peculiar to British government. Although a member of Parliament cannot relinquish his seat during the continuance of a Parliament to which he is elected, he may evade this rule by applying for one of certain offices, e.g. the stewardship of the Chiltern Hundreds or of the Manor of Northstead, offices under the crown which automatically vacate his seat. Application for one of these offices has sometimes under exceptional circumstances been refused, but ordinarily the Treasury will give the office, the duties of which are merely nominal, to any member who applies. The office is resigned as soon as its purpose is served, or retained only until the appointment is revoked in order to make way for another applicant. Another peculiarity is that until recently under the Statute of Anne (1705) the acceptance of a ministerial appointment rendered the holder's seat vacant but did not disqualify him for reelection. This statute, however, proved inconvenient in practise, since ministers of the crown had to submit themselves for reelection at a time when they were or ought to have been fully occupied with the duties of their new offices, and it was abolished by act in 1926 with the general approval of all parties and the public.

By-elections in Great Britain have always been regarded as matters of great importance. It is held that they indicate the trend of public opinion, and a succession of results unfavorable to the government of the day is taken to herald its approaching defeat at the next general election. Conversely a success or series of successes for the government has a heartening effect upon its supporters, and there is at least one instance in which a government was led to dissolve Parliament prematurely in consequence of an unexpected success at a by-election. In 1880, because of a conservative victory in a by-election at Southwark, Lord Beaconsfield as prime minister of a Conservative

cabinet dissolved the Parliament elected in 1874, although it had nearly another year of its term unexpired, only to find that "one swallow does not make a summer." His large majority in the House of Commons was entirely swept away in the general election which followed, and his place as prime minister was taken by his rival, Gladstone, leader of the triumphant Liberal party.

In some cases the polls for municipal councils and state legislatures may be taken as indicative of the trend of electoral opinion on national issues and thus have the same significance as by-elections. For example, in Germany, where an efficient party machinery functions throughout the year, the results of an election to a state diet reflect very clearly the relative strength of various parties in the particular territory. Generally, however, local elections are held on issues different from those important in a national election and the voters are not apt to follow the national party alignments. On the whole the same is true of congressional elections in the mid-presidential years in the United States. Time and again during an uninterrupted succession of Republican administrations the Democratic representation in Congress has increased in these elections. Only under exceptional circumstances may they be taken as significant of impending change in office or policy. A vivid recent example is furnished by the congressional elections preceding the retirement of Woodrow Wilson in connection with the League of Nations issue. The fate of the Democratic candidates was generally interpreted as a repudiation of the policies of President Wilson. It must be noted, however, that on this occasion the president had taken the rather unusual step of issuing a personal appeal for the candidates.

BY-LAW. The term by-law, by derivation the law of the borough, but early applied to the local legislation of manor, vill or guild for the regulation of the trade and agriculture or of

the health, safety and morals of the community, has gradually been extended and now includes, first, public laws enacted by governing bodies of municipal corporations; second, executive regulations of local application (*cf.* By-Laws under the Salmon Fisheries Act of Great Britain); and third, the rules of private corporations or associations enacted by the members for their governance in the transaction of business and for the definition of their relations to the association and to each other. In the United States the tendency has been to restrict the term to this last category and to use the terms ordinance for the legislation of municipal corporations, and rules and regulations for that of executive bodies.

The inexact logic of analogy by which the meaning of by-law was extended in Anglo-American jurisprudence has made it a term which cuts across the more precise categories of continental law, where it finds no counterpart. In the Anglo-American system different legal rules have necessarily been applied to the various forms of by-laws. The underlying concept of by-laws as rules or laws effective only for a locality or for a group explains the different uses of the term. In the case of associations by-laws are a mechanism of self-government by contract; among legislative forms they become an important device for flexibility in local government.

Originally by-laws were formulated by the appropriate local courts in the exercise of their feudal jurisdiction, independently of charter rights, and could with difficulty be distinguished from a simpler form of local legislation, the declaration of custom by those courts. As legal theory crystallized, by-laws were "presumed" instead of being regarded as equivalent to custom, and later with the triumph of central government "presumptions" of lost charters and of municipal incorporation often furnished their sanction. Today, except for unincorporated associations, by-laws are issued under enabling statutes or charters, which define their scope and in the field of government have become a form of delegated or subordinate legislation.

Doctrines of judicial control of by-laws developed during the struggle for centralization in England and took color from it. The king's court early claimed the right of review of local legislation and formulated the pregnant rules that by-laws must be reasonable and in accordance with the law of the land. These rules were

applied to corporations, private and municipal, with the additional requirement of conformity to a strictly interpreted charter, and the doctrine of delegated powers of local officials—a direct contrast to the continental theory of general powers—was formulated. In England, by statute, an executive check is usually placed upon governmental by-laws through the requirement of approval by a central official. Since the American invention of the contract theory of charters was not extended to municipal corporations, to which the doctrines of agency do apply, legislative control of municipal by-laws may be exercised in the United States by the alteration of the powers granted by charter. On the continent such control is executive and is exercised by central officials or administrative courts.

BY-PRODUCT. A by-product may be defined as a product or material which is produced, or the production of which is materially facilitated, as an incidental result of the production of something else. It is a minor element in a system of joint products. Meat packing affords an outstanding list of examples, including hides, leather, fertilizer, glycerine, glue bristles, etc. The chemical products of the distillation of coal afford another list of amazing extent and variety. Examples of a different sort include freight to fill cars which would otherwise move empty, special uses of electrical current at times when the central station has spare capacity and the expansion of large packing houses into the distribution of general foodstuffs as an incident to utilizing the system of refrigeration and distribution built up for the sale of meat products. By-

products in the stricter sense result from utilizing the varied constituents found together in products of nature. In a wider sense they result from utilization of spare capacity in plant or organization.

The utilizing of by-products has progressed from the stage in which only the more important materials are recovered and, in most cases, sold to separate concerns for manufacture, to the present stage in which substantially every material is typically worked up into finished form in departments of one concern.

The modern types of by-product recovery afford a powerful stimulus to large scale production, since the gains are only available when even the least plentiful constituents are present in quantities sufficient to pay for processes of recovery which are often more complex than the main process and involve a larger minimum investment of capital. They must also often reimburse the heavy expenditures on organized chemical research which have made the modern developments possible.

The classic statement of the law of value in such cases is that of John Stuart Mill ("Of Some Peculiar Cases of Value," *Principles of Political Economy*, ed. by W. J. Ashley, London 1909, bk. III, ch. XVI): "Cost of production does not determine their prices, but the sum of their prices . . . their natural values relatively to each other are those which will create a demand for each, in the ratio in which they are sent forth by the productive process." To fill out this basic principle it is necessary to take account of: the special cost of working up each product; cases in which the demand will not take the whole quota of a given product and therefore the special cost becomes the only cost affecting value; the existence of marginal products who handle only a part of the products; and the possibility of altering the proportions of the different products, as by selecting breeds of sheep for wool or for mutton, or by "cracking" oils to increase the yield of gasoline if its value will cover the costs of the cracking process at the sacrifice of other products.

Cost accounting divides the costs of the basic material and process among the various products, even though such division may be economically illogical. Such divisions may become matters of public interest: witness the charge that American meat packers reduce their apparent profits on meat by arbitrarily low "transfer prices" on materials to the by-product departments. This problem is intensified if one

element becomes a "public utility" subject to price regulation, as in the case of "giant power."

BYNKERSHOEK, CORNELIUS VAN (1673-1743), Dutch jurist. After ten years devoted to the study and practise of law Bynkershoek was appointed judge in 1703. In 1724 he rose to the position of presiding judge of the Supreme Court of Appeals for the provinces of Holland, Zeeland and West Friesland, serving until 1743. He was thus brought into practical contact with problems of international maritime commerce and of diplomatic rights and immunities, upon which subjects he was to write with enduring effect.

Bynkershoek is to be considered one of the founders of modern international law. In 1702 he wrote *De dominio maris dissertatio* (2nd ed. Leyden 1752; photographic reproduction with tr. by R. V. D. Magoffin in *Classics of International Law* series, vol. xi, Oxford 1923), in which he largely followed Grotius' doctrines of *Mare liberum* as modified by the more mature *De jure belli ac pacis*. In 1721 he published *De foro legatorum* (Leyden, French translation by Jean Barbeyrac as *Traité du juge compétent des ambassadeurs*, The Hague 1723) and in 1737 *Quaestiones juris publici* (2nd ed. Leyden 1752; book i tr. by P. S. Du Ponceau as *A Treatise on the Law of War*, Philadelphia 1810). Bynkershoek's method varies somewhat with his subject, but in general he relies more upon the custom of nations and Roman law and less upon the law of nature than did his predecessors. *Usus* and *recta ratio* are to him the chief supports of international jurisprudence. However, it is usually only when custom is lacking or its weight of authority uncertain that he is a strenuous advocate of right reason as a source. *Recta ratio* is then *juris gentium magistra* but it is a *ratio* more reliant upon Roman law than

upon the law of nature. His work has a logical lucidity not present in the writings of some of the previous civilians. Although he was not a complete systematizer he revealed great strength in the treatment of specific doctrine, and many of the principles enunciated by him are to be found in international law today. It was he who supplied as a basis for the doctrine of marginal waters physical control to the point "where the power of men's weapons ends," that is, by cannon shot of the then range of three nautical miles from shore. This was the origin of the "three mile limit" rule. Bynkershoek's other noteworthy works are in the field of Dutch and Roman law.

BYRON, LORD, GEORGE GORDON (1788-1824), English poet. Although he left no body of political writings he always concerned himself with politics. His career has a double interest for the social scientist. First, as the youthful champion of the Luddites during his brief appearance at the House of Lords, as the friend of Burdett, Hobbhouse and other gentlemanly radicals, as a Carbonaro in Italy and finally as the Prometheus hero and victim of Missolonghi, Byron gave fire and color to a liberalism whose Bentham and Mills had very little of either. The memory of his life and the reality of some of his poems (notably the *Prisoner of Chillon* and the lines beginning "They never fall who die in a great cause" from *Marino Faliero*) inspired suppressed nationalists and other underdogs throughout the century. The crop of Byrons which sprang up in other European literatures—Pushkin, Espronceda, Heine—was usually politically in revolt, sympathetic with the oppressed, contemptuous of "legitimacy." Second, Byron was the poet of social as well as of political revolt. In this second role he was less known on the continent than in his liberal and nationalist role; otherwise men like Treitschke could hardly

have admired him so much. But in England the poet of the *Vision of Judgment* (1822) and of *Don Juan* (1820-24) was known as a menace to society. These satires are directed against what seemed to Byron the smugness, sentimentality, intellectual laziness and economic selfishness of the English middle class. Byron attacked Victorianism while Victoria was in her cradle; his "cant" is an anticipation of Matthew Arnold's "philistinism." These poems are of course purely satirical; there is no attempt to put anything in the place of the English middle class.

BYZANTINE LAW. See LAW.

CABANIS, PIERRE JEAN GEORGE (1757-1808), French physiologist and moral philosopher. After varied literary efforts Cabanis chose medicine as his profession and from 1795 until his death taught at the École de Médecine at Paris. He was one of the group of *idéologues* who met at the salon of Mme. Helvétius at Auteuil and was the intimate friend first of Mirabeau and later of Condorcet. It was he who wrote the four tracts on education found among Mirabeau's papers. Cabanis published many books and pamphlets on scientific, philosophical and political subjects, but his great contribution to social thought was his anticipation of naturalism and positivism in sociology. In a series of six memoirs, read before the Institut de France in 1796 and 1797, he was the first to maintain and to attempt to prove that moral and social facts are linked to causes and that the same methods must be employed in the "moral sciences," which he considered "no more than a branch of the natural history of man," as in the physical sciences. These memoirs, with six others relating to the same subject, were published as *Rapports du physique et du moral de l'homme* (2 vols., Paris 1802; new ed. by L. Peisse, Paris 1844). Here is to be found Cabanis' analysis of the effects of age, sex and climate on morals. Through his disciple Richerand he exercised great influence on Stendhal, Saint-Simon and especially on Auguste Comte.

CABET, ÉTIENNE (1788-1856), French communist and social reformer. Cabet was educated as a lawyer, became a director of the Carbonari and devoted himself to democratic propaganda. In 1830 he was appointed *procureur général* of Corsica but was removed on account of his radical attacks on the French government. Elected deputy in 1831 he founded the *Populaire*, a newspaper of wide circulation among the working classes.

Because of his inflammatory denunciations against the government Cabet was exiled; he lived in England for five years, where he came under the influence of Robert Owen, and returned to France a convert to communism. He expounded his theories in the famous *Voyage en Icarie* (Paris 1840, 5th ed. 1848), a description of a utopia in which the government alone engages in commerce and supervises work and education. The only unit outside of the government is the family, which remains under the leadership of the head of the family.

Ardent disciples rallied about Cabet and raised subscriptions to finance a vanguard which sailed for Texas in 1848 to establish an Icarian city after Cabet's model. Cabet joined his disciples the next year, bringing with him new converts, and the Icarian city was created at Nauvoo, an old Mormon town in Illinois. A fifty-year transition period was supposed to precede the establishment of complete communism. At first the colony prospered but disagreements developed and in 1856 the founder and two hundred of his followers abandoned the settlement. After Cabet's death the colony moved to Cheltenham, Iowa, and later to Corning, continuing to follow in large measure Cabet's ideas. But economic difficulties cropped up continually and finally in 1895 New Icaria, the last community inspired by Cabet, was abandoned.

There is little that is original in Cabet's thought. He was opposed to all violence and expected his utopian communism to triumph over the existing order by force of example and conversion.

CABINET, in government, is a council composed typically of chiefs of administrative departments, functioning as advisers of the head of the state on questions of policy and administration. The British cabinet was the model more or less closely followed by others. Originally it was a committee of the Privy Council which had become so large that committees were necessary in order to get business done. Until after the revolution of 1688 the cabinet, as an institution, was inchoate. Under William III and Anne the principal officers of state designated by the crown constituted a cabinet, but cabinet government—i.e. responsibility to the legislature—was yet to develop. Under the Hanoverians this group of high officials increased and by 1761 it included twenty-one persons. This was partly due to the fact that when a post was once raised to cabinet rank there was a tendency to continue it and partly to the fact that the sovereign by making a personage or post of cabinet rank could extend his influence. Hence the real business of government came to be largely transacted by an inner cabinet, as in the "private meetings" at the home of Sir Robert Walpole, who was the first real prime minister. This inner cabinet was a group of five—the first lord of the Treasury (who at that time was also chancellor of the Exchequer), the two secretaries of state, the lord president of the Council and the lord chancellor. The membership of this group was approved by the king and by 1783 when the really important officials had been taken into it—the first lord of the Admiralty, the chancellor of the Exchequer and the Lord Privy Seal—it had completely supplanted the larger cabinet.

As the business of the state became more complex the cabinet inevitably increased. The elder Pitt had only six or seven colleagues. Peel had twelve. The Derby cabinets of 1853 and 1867 numbered thirteen and fifteen. Lord Salisbury's cabinets had from sixteen to twenty members. Asquith's pre-war cabinet had twenty members of whom seven were peers. During the war the number reached twenty-three. When Lloyd George took office in December, 1916, he made some sharp departures from accepted practices. He created a war cabinet of five persons of whom two were ministers without portfolio. The war cabinet coordinated and directed the

work of the administrative departments, but it did not include such important officials as the secretaries of state for war and for foreign affairs. There had long been a distinction between the ministry, that is, the whole group of executive officials, and the cabinet, a selection of this group, collectively responsible to the legislature. In Lloyd George's administration executive decisions were taken by the small war cabinet and communicated to the members of the regular cabinet.

Meetings with neither formal agenda nor minutes had long been a distinctive characteristic of the British cabinet. Freedom in discussion and informality in decision had been considered indispensable to efficiency. The informal functioning of the cabinet was in part due to the fact that the king did not attend its meetings. This had not always been the case; royal absenteeism resulted from the inability of George I to speak English—a tenuous thread on which was hung an important constitutional convention. In France some informality has been sought in the Conseil de Cabinet, which is not attended by the president of the republic and which considers political matters that do not concern the titular executive. A Conseil des Ministres, however, is held at the Élysée and the president presides.

The war made the maintenance of the British cabinet traditions impossible. A cabinet secretariat was set up, which kept a record of decisions and was of much importance during Lloyd George's coalition government of 1918-22. The importance of the secretariat was greatly reduced when the Conservatives came into power, but it has been retained as a recording agency.

In Great Britain cabinet ministers are almost invariably selected from Parliament, but there have been a few exceptions to this rule. Thus Gladstone was without a seat for six months in 1846-47 while he was colonial secretary. In continental countries membership in the legislature is not required for membership in the cabinet. In France a number of non-parliamentarians have been ministers—principally for war and marine. Cabinet making on the continent, moreover, is somewhat simpler than in Great Britain because ministers have the right of access to both branches of the legislature. British ministers may attend and speak only in the House to which they belong and are represented in the other chamber by proxy, i.e. by under secretaries. For this reason it is important that there be certain cabinet members in the House of

Commons to answer the criticisms of the body to which they are responsible. Since Walpole was chancellor of the Exchequer in 1715, that office has always been held by a member of the House of Commons because of the special interest of the elected chamber in the control of the purse.

Walpole's government included only one other commoner, and in the younger Pitt's cabinet all members except the head were peers. With the development of the system the Commons has been more and more heavily represented. Since the Reform Bill of 1832 only seven peers have been prime ministers, the last being Lord Salisbury. In view of the fact that the House of Lords has been shorn of much of its authority and that labor is inadequately represented there, it is probable that all future prime ministers of Great Britain will sit in the House of Commons. French prime ministers give most of their posts to the Chamber of Deputies, for the confidence of that body is of more importance to the administration than that of the Senate. Under the Third Republic there have been four times as many deputies as senators in cabinet posts.

Under the cabinet system British politics has developed two powerful groups, those in the cabinet and those in the opposition, which hopes to and probably will eventually become the government. Only when a new party comes into power is there a wholly new cabinet personnel, as in MacDonald's government of 1924. When MacDonald returned to power in 1929 he made up his cabinet largely from the membership of his earlier administration. Over a period of fifty years Gladstone was a member of nine cabinets. Many of his colleagues served with him in successive cabinets. It is true that in 1880, after Gladstone's party had been long out of power, he had ten new colleagues, but in 1886 he had only four, and only five in 1892.

In France rotation in office is rapid because of frequent changes of government. The range of choice of possible cabinet members is far wider than in Great Britain, where through their positions in the party, their standing in the country or their ability as debaters and administrators certain politicians inevitably become cabinet members. In France no cabinet can be formed except by a coalition of several political groups of the chamber. Several different kinds of coalitions are possible. The same Chamber of Deputies may support one cabinet oriented to the Left and a succeeding one oriented to the Right.

Persons of "cabinet timber" in France are called *ministres*, and the number of *ministres* who have served as ministers is large.

In both the British and the continental systems the return of a party to power means as a rule a cabinet composed in large part of experienced ministers. A politician who has once been prime minister is fairly certain to head the government again on the return of his party to power. Thus in France sixteen presidents have headed fifty-one administrations. In seventy-eight cabinets the average member has served in three. Briand has served in twenty-one cabinets; Bourgeois, Eynac and Leygues each in fourteen; Barthou, Delcassé, de Freycinet and Loucheur each in thirteen. Occasionally a number of changes of government may occur and the position of a particularly important minister will be unaffected. Thus Briand remained as foreign minister in France under several different premiers, and Stresemann's post at the Wilhelmstrasse was undisturbed by cabinet crises.

There is in European systems no tradition that a president of the council shall not figure in a later cabinet merely as a minister. Not since Lord John Russell has a British prime minister been a member of a subsequent cabinet (the case of Balfour during the war was exceptional) but there is no reason why it should not happen again. In France and other continental countries ex-premiers frequently become ministers.

In the United States the cabinet differs widely from the European type. When the heads of the principal departments of the government meet with the president they are called a cabinet, but here the resemblance to the English body ends. The members of the cabinet have no connections with the legislature. They have no collective responsibility. Each member is individually responsible to the president, but the president has no control over departmental policy except through the removal of a secretary and the appointment of another who will act in accordance with presidential wishes. The president can, if he likes, treat cabinet members as chief clerks rather than as associates. He can make cabinet meetings purely perfunctory or dispense with them altogether.

Under the constitution the president was empowered to "require the opinion in writing of the principal officer in each of the executive departments." "Heads of departments" were apparently contemplated, for the constitution allows Congress to vest in such heads the appointment of inferior officers. On this slight con-

stitutional authority and on the custom, unbroken since its establishment by Washington in 1792, of consulting with the principal officers of the government, rests the institution of the American cabinet. The term itself did not appear in a federal statute until 1907.

Three departments, for state, war and the treasury, were established by the first Congress in 1789. Another important official, the attorney general, the legal adviser of the president, was necessary from the beginning, but not until 1870 was he made head of the Department of Justice. Almost at once Washington brought these four officials together in an advisory council. By 1793 this council had been dubbed the cabinet. Vice President Adams attended one of the early meetings, but apparently the vice president was thereafter excluded until President Harding invited Vice President Coolidge to attend meetings of his cabinet in 1921, a practise which was not long continued.

The threat of war with France in 1798 led to the creation of a separate Navy Department as distinct from the War Department. In 1829 the postmaster general was raised to the dignity of a department head. The Department of the Interior and the Department of Agriculture were created in 1849 and 1889 respectively to take over the work of previously existing bureaus and commissions. A Department of Commerce and Labor was established in 1903, and ten years later was divided into the two departments of Labor and Commerce.

The American cabinet meets in secret and no records are kept; only brief *communiqués* are issued to the press. One can learn what cabinets do only from such sources as the memoirs of John Quincy Adams, the diary of James K. Polk, the diary of Gideon C. Welles and similar records. From the Civil War to the World War practically nothing was published on cabinet business, but revelations made by certain members of President Wilson's cabinet—Franklin K. Lane, David F. Houston, A. S. Bursleson and others—throw light on President Wilson's indisposition to consult his cabinet on questions of policy.

Presidents cannot permit one section of the country to be overrepresented in their cabinets, even though selection from the various sections may involve the acceptance of men of mediocre ability. Nevertheless six states have contributed more than half of the incumbents (New York, 45; Pennsylvania, 38; Massachusetts, 31; Ohio, 23; Virginia, 19; Maryland, 15) and ten of the

states have never furnished a member of the cabinet. Only rarely is a secretary chosen from the opposite political party. The Post Office Department is politically the most important position and frequently goes to the chairman of the National Committee. Occasionally the State Department is entrusted to an unsuccessful candidate for the nomination. The custom is growing that the Department of the Interior should be assigned to a westerner.

In the American cabinet brevity of tenure is the rule. One in seven of the cabinet appointees since the time of Washington has sat in more than one cabinet. Less than one half of these has previously served in the House or the Senate.

The president can recruit his cabinet much as he wishes and is restrained only by a fear of popular disfavor or senatorial objections; the Senate as a rule allows the president a rather free choice in the selection of his heads of departments. Only on four occasions has the Senate actually rejected nominations. From 1868, when it refused to confirm Judge Stanbery as Johnson's attorney general, down to its two refusals to confirm Charles B. Warren as President Coolidge's attorney general in March, 1925, the Senate has interposed no veto on cabinet appointments. On three occasions the Senate has objected to secretaries who were given recess appointments. That the president is allowed such independence of choice, limited only by party pressure, exigencies and personal considerations, is at once an application of the separation of powers theory and an indication of the subordinate position of the cabinet.

CABINET GOVERNMENT. Modern constitutional government presents two sharply distinguished and opposed types: the cabinet

system which obtains in Great Britain, the British self-governing dominions and in western Europe generally; and the congressional system which is found throughout the Americas. As the government of the United States is the purest example of the congressional type and has served as the pattern for other governments which have adopted this form, so the government of Great Britain is the most perfect example of cabinet government and has constituted the model which has been widely copied by the British dominions and by other European countries. These two types embody fundamentally antithetical political theories. Congressional government is based upon the doctrine of the separation of executive, legislative and judicial powers and operates through an elaborate scheme of checks and balances. The distinctive characteristic of cabinet government is the union in a responsible collegiate ministry of the supreme direction over both law making and administration; in contrast to a system of checks and balances it embodies the principle of concentrated authority under strict control. The cabinet in this type is the central shaft to which all the other agencies of government are geared. The individual members of the cabinet are the heads of the several departments of the administration; collectively it shapes the program of legislation which is submitted to parliament; and from it emanate the broad and general public policies with respect to both foreign and domestic questions. In this system the head of the state occupies a position of great dignity, but practically all authority, nominally vested in him, is in effect exercised by the ministry, which assumes full responsibility for acts performed in his name. The unity and collective responsibility of the cabinet are achieved through the prime minister, who is the keystone to the cabinet arch. His associates in the ministry are appointed on his nomination, and his death or resignation immediately results in their surrendering their offices.

In cabinet government the ministry is collectively responsible immediately to the legislative body, or particularly to its more popular branch, and ultimately to the electorate. Upon a vote of lack of confidence or the definite defeat of an important ministerial measure by the parliament the ministry either resigns as a body and gives place to one drawn from the opposition party or exercises the prerogative of parliamentary dissolution whereby it brings the sitting parliament to an end and through a new election appeals to

the voters upon the issue which has been raised. If the result of such an election is favorable to the ministry it remains in power; otherwise it surrenders control to a ministry formed from the opposition. Ministerial tenure depends at all times upon the maintenance of a majority in the popular branch of the legislative assembly. Within any party there are always somewhat divergent elements. In a legislative assembly the majority party always includes some whose adherence to the ministry is somewhat tenuous. These more or less independent members may on the occasion of a vote on some specific measure withdraw and assist in transforming the majority into a minority. Or such a considerable defection may occur on some major question of policy as to result in the successful passage of a vote of lack of confidence. Casual ministerial defeats on minor questions are likely to be disregarded, unless cumulatively they indicate such a definitely growing opposition as to lead the ministry to voluntary resignation.

Parliamentary control of the ministry is, however, balanced by ministerial leadership and control of parliament. The ministers are as a rule members of parliament and leaders of the party in the majority. Under the rules of procedure ministerial or government measures have precedence. Indeed the entire program of legislation is largely shaped and dominated by the ministry. Through the threat of dissolution the ministry can often preserve its control over a restive parliament. Dissolution involves an election with all the attendant expense to individual members and the possibility of their failing of reelection. Thus the threat by the ministry to dissolve is a powerful instrument in holding supporters in line and in reducing the vigor of attacks from the opposition. It is, however, a weapon which becomes less and less effective as the term for which the legislative body is elected draws toward its close, and proximate dissolution is anticipated as inevitable in any case. In France, although the constitution vests the power of dissolution in the president and senate, this power has not been invoked since 1877. Practically it does not exist. The lack of this check constitutes one of the chief causes for ministerial instability in France.

Cabinet government functions satisfactorily only where certain conditions are present. It is essentially party government and presumes the existence of two, and only two, great rival parties between which the pendulum of power swings. The party which is in a majority in the legisla-

ture is vested with the full authority of government and responsible for achieving a political, legislative and administrative program. The party in opposition performs the role of critic and seeks at all times to put the government in a minority and thus secure the reins of power. Politics thus assumes the character of a great game in which two teams compete, the one the team of the "ins," the other that of the "outs." Where, as on the continent, a group system of parties obtains, no one of which possesses an independent majority, the ministry rests upon the unstable basis of a coalition of partisan groups. The shifting realignment of such groups results in frequent and rather meaningless changes in the ministry.

Not only is a two-party system essential to the normal operation of cabinet government, but each of the two parties must include within its membership representatives from all substantial sections of the community. Parties must cut across the various class, racial, occupational, confessional and geographical divisions of society. Otherwise the divisions into parties will remain static and every transfer of power will involve a crisis which may seriously disturb the whole legislative and administrative process. It is an essential feature of cabinet government that there shall be an effective opposition which shall subject the government to criticism at all times, with respect to both administration and legislation, and which is ready to take over the reins of government whenever a shift in political sentiment in the legislative body, or ultimately in the country, permits. When parties are based upon economic interest, or upon social, confessional or sectional attachments, such shift in sentiment does not occur. Only by the slow process of social change is the relative strength of parties altered. If an agrarian party is in power it retains control until the process of industrialization has transformed the social structure of the community. There can be no normal swing of the pendulum. A condition of party fluidity is found only in societies of a high degree of social homogeneity. Permanently dissident groups, such as the Irish Nationalists in Great Britain before 1922 and the French Canadians in Quebec, always present impediments to the proper functioning of cabinet government. Where the entire party structure consists of such inflexible and rigid social strata, as is frequently the case upon the continent, cabinet government is theoretically quite anomalous.

A further condition for the perfect working of

cabinet government is a unicameral legislature, or such a complete subordination of the upper chamber to the popularly elected house that the latter's will can within a reasonably short period be made absolutely effective. The relationship of control and responsibility between the ministry and the legislature which characterizes cabinet government is largely nullified where two chambers, differently constituted and often committed to quite antagonistic policies, equally claim the right to reverse a ministry. Responsibility under a bicameral system is diffused and scattered. Either the ministry under such conditions recognizes responsibility to both houses and consequently is weak and incapable of exerting real leadership or it takes advantage of the divided parliament to rise above effective control and becomes practically irresponsible.

Even in Great Britain, where cabinet government functions most satisfactorily, these theoretical conditions do not fully obtain. The Irish Nationalists constituted for a period of fifty years, prior to the establishment of the Free State, a third party which at times seriously embarrassed the working of the cabinet system. In the later phases of the Great War party lines practically disappeared and a coalition ministry governed almost without parliamentary control. The emergence of the Labour party in recent years has raised the pertinent question as to whether British government will not have to adapt itself to a permanent system of three parties. Both the first and second Labour ministries have lacked a Labour majority in the House of Commons, and their tenure of office has been extremely precarious, depending upon sufferance of the two other parties, particularly the Liberals. The Labour governments have frequently been defeated in the Commons. The opposition in inflicting these defeats has not, however, desired to bring about the retirement of the ministry. A minority government holding power through the forbearance of the opposition is, however, at best a weak government, unable to achieve its program effectively. It is constantly hampered by the necessity of conciliating the opposition. Whether this situation will persist or whether the Liberal party will eventually disappear as an effective factor in British politics is a matter of speculation.

In France the kaleidoscopic range of political groups from extreme right to extreme left has in recent years been somewhat stabilized by the formation of blocs consisting of a number of such groups. During the decade following the

war two such blocs, the Union Nationale, composed of moderate and conservative elements, and the Cartel des Gauches (Left Bloc), seemed to offer a possible basis for a permanent two-party system along Anglo-American lines. But the Left Bloc, after winning the election of 1924, dissolved in the succeeding years when faced with the serious problem of stabilizing the franc. The victory of the Union Nationale in the election of 1928 was in reality a personal victory for Poincaré, and with the accomplishment of his work of financial stabilization this bloc also gives evidence of speedy disintegration. Extreme fluidity and instability are fundamental characteristics of French political parties and explain in large measure the relative failure of cabinet government in that country.

Cabinet government in its normal operation is a strong form of political organization, capable of speedy and effective action. In emergencies the cabinet is able to draw to itself all the powers of the state. This strength lies largely in its simplicity, and since the government rests upon the public opinion of the community the danger of despotism is slight. Under cabinet government reliance is placed upon understandings and a common willingness to play the game according to the rules rather than upon a complex system of legal arrangements and determinations. It necessitates on the part of the people a high degree of political education and capacity.

CACHET, LETTRE DE. A lettre de cachet was, in general, a document by which the king of France gave an order to an individual on a matter affecting his own service; it was countersigned by a secretary of state and sealed (*cacheté*)

—hence the name, in contrast to letters patent which were not sealed. In the narrower and more common sense, however, the expression had reference particularly to orders by which the government, on its own authority and without judicial formalities, imprisoned or exiled an individual.

Theoretically this practise was justified by the principle that the king was the sovereign judge from whom emanated all law and justice. He could therefore, when he chose, pronounce judgment on one of his subjects without being compelled to observe the forms prescribed for ordinary judges and without having to indicate the reason for his decision. The kings of France early made use of this right, but it was in the seventeenth and eighteenth centuries under the absolute monarchy that imprisonment and exile by lettres de cachet were most frequent. They were used for crimes against the safety of the state, for crimes of opinion, even for family affairs—thus a father might shut up a prodigal son or a daughter who refused the suitor he proposed; a husband might obtain the incarceration of his wife of whom he had reason to complain; a great lord might have a relative imprisoned for disgracing the family by his conduct.

Delinquents were usually imprisoned in the Bastille, which became famous on that account, but there were numerous other "royal castles" to house prisoners of lesser importance, such as the Château de Vincennes, the For-l'évêque in Paris (for actors), the Château d'If near Marseille, Pierre-Scize near Lyons, the Tour de Constance at Aigues Mortes or the Mont Saint-Michel. Hospitals and convents were used for the same purpose.

It is easy to understand how this convenient method of disposing of its enemies came to be abused by the government. It has been estimated that nearly 150,000 lettres de cachet were dispatched during the reign of Louis xv. The king, who was supposed to sign them himself, as a matter of fact allowed his name to be signed by a scribe; the minister who sent them, unable to investigate everything to which the letters referred, had to rely on his subordinates, clerks, superintendents or chiefs of police. Sometimes these subordinates actually received letters signed in advance, with the name of the addressee in blank so that a mere clerk might, in the name of the king, imprison anyone who displeased him. This was the principal method of prosecuting crimes of opinion. Jansenists, Quietists, Protestants, *philosophes* were im-

prisoned for having expressed opinions disapproved by the government. Voltaire, Mirabeau, Helvetius, Linguet were confined in the Bastille and their books burned. Lettres de cachet in powerful hands were a formidable weapon against liberty of thought and person.

Those whom it threatened soon protested against this practise. Voltaire, Montesquieu, Mirabeau, the *encyclopédistes*, repeatedly demanded its suppression. But it was primarily the expostulations of the *parlements*, of the *cours des aides* and of the *chambres des comptes* which created a wave of opinion against the lettres de cachet. "The result is, sire," declared the *cour des aides* of Paris to the king in 1770, "that no citizen of your realm is guaranteed against having his liberty sacrificed to revenge. For no one is great enough to be beyond the hate of some minister, nor small enough to be beyond the hate of some clerk." Among the attempts at reform under the reign of Louis XVI was the project formulated by Minister Malesherbes to abolish lettres de cachet, but this project failed. His defeat served only to discredit the monarchy still further and there is no doubt that this practise was important among the immediate causes of the revolution. The general condemnation of it by the three estates was revealed in the *cahiers de doléances* of 1789. It explains, moreover, why the Bastille served as a symbol of oppression to the Parisian populace. In August, 1789, the Constituent Assembly definitively condemned lettres de cachet in France when it proclaimed the principle that no man can be accused, arrested or detained except in cases fixed by law and according to the forms prescribed by law.

CADBURY, GEORGE (1839-1922), English social reformer. With his brother Richard he inherited from his father a small cocoa manufacturing business in Birmingham and together they developed it into an industry employing many thousands and operating all over the world. Concurrently with this achievement they both devoted themselves to social experiments, Richard on traditional lines, George more originally and adventurously. During his work in connection with the Adult School he became impressed with the degrading effect of crowded city life, and when in 1880 he and his brother removed their works into the country four miles outside of Birmingham he founded Bournville, which was destined to become the archetype of the garden city. Through this enterprise he attacked scientifically the problems of housing, town planning and land monopoly. He disclaimed any philanthropic purpose but sought to show how industrial England could be reconstructed on enlightened and economic principles. Ultimately he handed over the developed experiment to a trust on behalf of the nation as a working model of the fulfilment of his ideas. The modern movement in housing and town planning reform, not in England only but on the continent, especially in Germany, has derived largely from Cadbury's experiments.

Meanwhile he promoted and financed a movement that culminated in the establishment of national old age pensions with its corollary of national insurance, and he helped by his purse and by his influence through the *Daily News*, of which he had become the proprietor, to abolish the scandal of sweated industries. His benefactions were innumerable. They included a home for cripples, a resthouse for convalescents, many Quaker meeting houses and the Woodbrooke Settlement. The latter became the home of "modernism" in the Quaker movement and the nucleus of the Selly Oak colleges, which constitute a new type of social and religious university. His personal benevolences were ceaseless but they always aimed at a regenerative or constructive purpose. His greatest pleasures to the end of his days were his work in the Adult School at Birmingham and the almost daily dispensing of hospitality to the thousands of the poor of Birmingham, to whom his grounds at Northfield were always open for sports and fêtes. He took little part in public life and declined all honors.

CADET PARTY. See PARTIES, POLITICAL.

CAESAR, GAIUS JULIUS (102 or 100-44 B.C.). He was by birth a Roman of an unimportant patrician family, by political affiliation an adherent of the popular party. The support of the *Populares* secured his advance through the lower magistracies and his election as pontifex maximus in 63 B.C. Becoming consul (59 B.C.) with the backing of Pompey and Crassus, he displayed an utter disregard of constitutional practices, which incurred the undying hostility of the senatorial faction. By securing an extraordinary command in Cisalpine and Transalpine Gaul for a period of five years, later extended to ten, he was able to develop his latent military talents, create an efficient army devotedly loyal to himself and amass a huge fortune, as well as exercise an enduring effect upon the cultural history of Europe by adding the "Three Gauls" to the Roman Empire. Fear of his power led the Senate and Pompey to unite in an effort to procure his ruin, whereupon he appealed to arms to protect his life and his position (49 B.C.). Caesar emerged victorious from the civil war (46 B.C.), became master of the Roman world and was forced to face the problem of reorganizing its government.

Despite his previous championship of the *Populares* he now disassociated himself from all ideas of democratic rule and treated the commons as unfit to share in the government of the state. He abandoned completely the old Roman ideal of city-state imperialism and frankly accepted as the solution of his problem a world empire ruled by a deified autocrat of the Hellenistic type. This explains his acceptance of the permanent dictatorship and other unconstitutional offices and powers, his welcoming of divine honors, his degradation of the senate to a position of subservience to himself, his generous admission of provincials to Roman citizenship, his courting the title of king and his plans for the expansion of the Roman dominions into a world empire. In his system there was no place for the institutions and traditions of the republic, and it was the realization of this by the senatorial aristocracy which brought about his assassination.

Caesar's most important legislative measures were those affecting the reform of the calendar.

the regulation of the grain dole, the restriction of the guilds, the employment of free rural labor, municipal organization and extensive colonization enterprises. Many of his projects, however, remained for later ages to accomplish. Caesar's chief contribution to contemporary history was his preparation of Roman society for the principate established by his grandnephew Augustus; his legacy to the future was his imperial ideal which obtained full realization in the autocracy of Diocletian.

CAIRD, JAMES (1816-92), British political economist and pioneer in the development of scientific agriculture. He was influential in English agricultural circles for nearly half a century, first as writer, then as member of Parliament and finally as the incumbent of many offices in the governmental agricultural services. His report upon the condition of agriculture in England in the year 1850-51 was the most valuable since that of Arthur Young. This study convinced him of the desirability of reliable agricultural statistics and it was as a result of his unceasing efforts that the government finally began to issue such data in 1866. As a practical farmer Caird believed that English agriculture could be saved, despite the repeal of the corn laws, by the practise of high farming, i.e. by larger capital investment in manures and draining, a greater emphasis upon livestock and the intelligent use of scientific methods. The period of agricultural prosperity from 1853 to 1875, due in large part to the Crimean and American civil wars, appeared to substantiate Caird's opinion. But he failed to foresee the factors, such as cheapened transportation, which finally brought on the depression following 1875. It has been the contention of many that high farming was in the long run more harmful than helpful to English agriculture.

CAIRNES, JOHN ELLIOT (1823-75), Irish economist. Cairnes graduated from Trinity College, Dublin, in 1848 and upon the advice of a friend some years later began to read political economy. In 1856 he won the five-year appointment to the Whately professorship at Dublin University. He was admitted to the Irish bar in 1857 and appointed professor of political economy at Queens College, Galway, in 1859, and at University College, London, in 1866. *The Character and Logical Method of Political Economy*, the title under which he published his first course of lectures (London 1857, 2nd ed. 1875), was followed in 1862 by *The Slave Power* (2nd ed. London 1863), which was intended, in the author's words, "to show that the course of history is largely determined by the action of economic causes," and which was, at the same time, in the words of Leslie Stephen, "the most powerful defense of the cause of the Northern States ever written." He published numerous articles, on educational policy, the Irish land situation, and money and prices, some of which were embodied in his *Political Essays* (London 1873) and his *Essays in Political Economy Theoretical and Applied* (London 1873); and as his reputation grew, he came to exercise great influence upon public opinion and upon important public issues. The appearance of his chief economic work, *Some Leading Principles of Political Economy Newly Expounded* (London 1874), and the death of John Stuart Mill left Cairnes, in the judgment of his countrymen and of many others, the foremost living economist.

Cairnes' main purpose in writing *Some Leading Principles* was to defend Ricardian doctrines against the increasing attacks of critics and particularly against the final utility conception of Jevons. He always regarded himself as a disciple of J. S. Mill (see dedication to first edition of *The Slave Power*) and a member of the "orthodox" classical school. This was also the opinion of his earlier admirers among conservative theorists, such as J. L. Laughlin and Francis A. Walker. A different view was foreshadowed by Alfred Marshall, who from the first feared that Cairnes' effort to amend the classical doctrines was really aiding to overthrow them. As J. N. Keynes said later, the theoretical work of Cairnes helped "to shake faith in the finality of

the Ricardo-Mill doctrines." Yet in wide circles it considerably retarded the development of more consistent and tenable views.

Cairnes' narrow advocacy, in his earliest work, of the deductive and abstract method was refuted by his own best studies in historical causes, such as *The Slave Power*, and in statistics and observation, such as the essays on the Australian gold episode. His attempt to revive the wage fund doctrine after J. S. Mill had repudiated it was ingenious but futile. His discovery of the ambiguity in the term "cost of production," his rejection of Mill's use of the term in the sense of entrepreneur's monetary outlays, and his attempt to restore it to the meaning of sacrifice, pain or trouble only made confusion worse confounded. The "doctrine of non-competing groups," Cairnes' best known contribution to economic theory and terminology, owes its wide vogue to its eclectic, compromising character. Although superficially it appears to preserve the essence of the cost-of-production doctrine it virtually concedes the validity, over a large part of the field, of the value-of-produce explanation of price. It is in fact Mill's doctrine of reciprocal demand extended from foreign to a large portion of local and domestic trade.

FRANK A. FETTER

CALENDAR. A calendar, in the words of Durkheim, "expresses the rhythm of the collective activities, while at the same time its function is to assure their regularity." Even on the lowest stage of culture some time reckoning is a necessity to man. In the ever recurring changes of seasons, in animal and plant life and in the celestial phenomena, nature provides means for such measurement. The time of the day can be indicated by reference to dawn, sunrise, the position of the sun in the heavens; the time of the year by seasons and more precisely according to natural events—the sprouting and falling of the leaves, the appearance and rutting time of certain animals. Among nomadic peoples the time when the young are born is important; among agricultural peoples the cycle of agricultural occupations serves as a natural calendar. Although the year as the cycle of the seasons is well known to most peoples, by many it is not conceived as a period of a definite length. Thus agricultural peoples have sometimes an incomplete "year," from the beginning to the end of the agricultural occupations; the interval is passed over without counting. Social and reli-

gious life are regulated by, and come to center around, such natural calendars; fairly common are New Year festivals at sowing and especially at harvest times; in the far north winter, during which labor rests, is the time of festivals, hence the popularity of the yuletide; and half Africa assembles to dance on the nights of full moon. Among slightly more civilized peoples a short period not depending on natural phenomena but on the exigencies of social life may become a means of time measurement. Thus the market week of four to eight days is common; a well known historical example is the *nundinae* of ancient Rome. The Jewish sabbath was also probably a market day originally. Market weeks are sometimes comprised in cycles forming a kind of year as in West Africa and old Mexico, but among most peoples the year cycle long remains vague. Years are counted by counting seasons: he who has seen ten winters or harvests is ten years old. The years are not numbered but are referred to in terms of outstanding events: a war, a disease, in more developed civilizations such as Egypt or Babylonia the reigns of kings or annual changes in magistrates and public officers. Still later is the introduction of eras such as the Olympiads, the era beginning at the mythical date of the founding of Rome and that dated from the birth of Christ, which was introduced by the Christian calendriographer, Dionysius Exiguus, about 525 A.D.

As festivals and religious observances acquire a life and an importance independent of their connection with seasonal occupations, and as social life increases in complexity, a more exact system of time measuring becomes necessary. Time reckoning in the proper sense involves not only observation of changing events but calculation of units of time of a definite length. A moon month is the most easily observed, continuously repeated period of fixed length and may readily be subdivided into days distinguished by the shape and position of the moon. These traces of the use of a moon month may be found in almost all calendrical systems. Greater definiteness is achieved by the adoption of a list of month names covering the year. But the changes of natural life depend ultimately on the course of the sun and are consequently related to the risings and settings of the stars. The divergences between the lunar and the solar reckonings have caused difficulty to all calendar makers. A method of determining the true length of the solar year was early discovered by a few primitive peoples, and the Egyptians knew it

probably in the fifth century B.C. The calculation is based on the fact that the stars culminate every day four minutes earlier than the sun; consequently a day of the solar year is determined fairly accurately by indicating it as being the day of the first appearance of a certain star in the morning dusk (its heliacal rising), and the measurement of the time between two heliacal risings of a star fixes the length of a solar year. Since the solar year is approximately 365 days in length, while a twelve-month period (of the 29½-day month from one new moon to another) comprises 354 days and a thirteen-month period 383½ days, some adjustment is necessary to keep the months in their places in the year. Peoples who have a twelve-month system commonly add a month (intercalation) and those who have one of thirteen months leave out a month (extracalation) when needed, at regular or irregular intervals. Certain peoples have gone even farther in basing their calendars on the solar rather than on the lunar year. The Egyptians very early observed the heliacal rising of the star Sirius, called by them Sothis, which then corresponded with the beginning of the Nile flood, and thus conceived the idea of the solar year and introduced it, probably in 4241 B.C. Their twelve months, numbered but not officially named, each had thirty days, thus becoming subdivisions of the solar year rather than moon months. The year was completed $[(12 \times 30) + 5 = 365]$ by five epagomenal days belonging to no month. Even the 365-day year, however, does not correspond exactly with the time period of the earth's revolution, being nearly six hours too short. It is therefore necessary to insert an extra day about every fourth year to keep seasons and months in correspondence. Although Egyptian astronomers quite early understood these relationships of the various time periods, they were not actually embodied in the calendrical system, and their year remained a "vague" year.

Few early peoples developed so complex and exact a system of time reckoning as did the Egyptians, although the influence of their calendar can be traced widely throughout the world. The Babylonian calendar was a lunar calendar, adjusted to the solar year by intercalation. The Hebrews may have derived the practise of intercalation from the Babylonians; certainly after the Exile they adopted the Babylonian names of the months as well as some of their ritual features. The Persian calendar, which still prevails in those parts of the old

Persian empire independent of Moslem rule and which was carried into India by the Parsees, shows definite traces of Egyptian influence after the Persian conquest of Egypt under the Achaemenides. In particular it is based on the $360 + 5$ -day year. In India the enormous mass of local cults and festivals is based on a lunar year and a lunar zodiac, which was adjusted by early Hindu astronomers through the use of a five-year cycle with the insertion of an intercalary month in the second and fifth years. It is more difficult to reconstruct the early Chinese calendrical system, for the board which issued the official calendar yearly until the revolution of 1912 had undoubtedly been influenced by contact with western ideas introduced by the Jesuits in the seventeenth century. It is clear that the Chinese have had from early times a lunar month of 28 days named after the 28 lunar stations. In the official calendar, however, the lunar month has $29\frac{1}{2}$ days and the solar $365\frac{1}{4}$. In the measurement of longer periods of time the Chinese employ a curious sexagesimal cycle, traditionally based on a combination of the five elements with the twelve animals of the zodiac. The same cycle is applied to the day, which is divided into sixty parts.

Of recent years interest has centered in the problem of the origin of the Mayan calendar. Based on a cycle of 260 days, called the *Tonalamatl*, which had a magic significance as yet unexplained, and combined with the solar year in a 52-year cycle, the Mayan calendar is said to exhibit a high degree of scientific knowledge. Its analogies with the Chinese calendar have led such scholars as W. J. Perry and Elliot Smith to hypothesize a close connection of the Mayan culture with that of Asia, but this claim is widely disputed.

The development of any such complex calendrical system requires not only the discovery of scientific principles but the continued application of expert skill in the management of the system. The control of the calendar naturally fell first into the hands of the priests, who were not only the possessors of knowledge but the directors of those religious festivals on which the calendar rested. Long after the Exile it remained the privilege of the Jewish high priest at Jerusalem to announce the intercalary months and thereby to fix the time of the celebration of the chief feasts, sending messengers to the Jews of the Diaspora. Powerful rulers usually took over the privilege. From the time of Hammurabi until 538 B.C. the Babylonian kings issued edicts in-

serting intercalary months at the advice of the astronomers, who were probably priests. The creation of the Chinese board for the official calendar is attributed to the Emperor Tao (c. 2400 B.C.). Control of the calendar, with all its implications as to the control of religious rites and popular festivals, has been an important instrument of political centralization as well as of cultural change. A variety of local calendars, based on local cults, existed in the old Sumerian cities. During the supremacy of Babylon the calendar was unified and thus a calendar brought into general use which combined the features of various of the older calendars and was of no small importance in the maintenance of the political supremacy of Babylon.

The very importance of the calendar to the whole social system makes almost inevitable the lapse of considerable periods of time between the progress of astronomical knowledge and change in the method of time reckoning. The calendar has repeatedly been an important cause of social conservatism. Even in Egypt, although knowledge of the astronomical cycles was widespread, the religious calendar was only irregularly adapted to it. Of the earliest Greek calendar we know nothing except that it had moon months. The well known Greek luni-solar calendars of the historical age had a religious character and were circulated from the oracle in Delphi in the seventh and sixth centuries B.C. They comprised a cycle of eight years with three leap years of thirteen months.

This year cycle of $365\frac{1}{4}$ days, which emanates from Egypt, has become through its adoption as the basis of the Julian calendar the fundamental calendrical system of the Occident. The early Roman calendar had been of the luni-solar type, administered by the pontifices. They had used their control of its correction for personal and political motives. One of the steps taken by Julius Caesar in the building up of his power was the reform of this calendar. Relying on the technical aid of the Alexandrian astronomer Sosigenes in 46 B.C. he introduced the Egyptian solar year, improved by the addition of an intercalary day every fourth year and subdivided into months of somewhat unequal length with Roman names. Quintilis and Sextilis were renamed Julius and Augustus in honor of Caesar and Augustus respectively. About this same time the seven-day week became popular, and with the prescription of the celebration of Sunday Christianity introduced over a wide area the boon of regularly recurring

rest days. It was also due to the Christian church that a troublesome feature of the luni-solar system survived. For Christianity inherited from Judaism the movable Easter festival and its connection with the full moon. The Jewish rule was remodeled so that Easter was celebrated on the first Sunday after the first full moon after the spring equinox. This permits variations of 35 days in the date of Easter; the stabilization, or "fixing," of this religious festival has concerned all calendar reformers of the modern world, and a solution of the difficulty is still to be found. Even the year of $365\frac{1}{4}$ days does not correspond exactly to the length of the true solar (tropical) year, being about eleven minutes too long. All long established calendrical systems have had to face this difficulty. Its recognition was involved in the various cycles of time periods which have characterized most developed systems. The Egyptian Sothis cycle of 1461 years, representing the time which elapses between each exact correspondence of the heliacal rising of Sothis with the New Year's day of the vague year, was of this character. The Metonic cycle of 19 years, traditionally inaugurated in Greece in 432 B.C., forms the basis for a cycle aiming to bring about an exact correspondence between the lunar and the solar reckoning. But in practise few calendars have been adapted to such cyclical variations, and consequently intermittent "corrections" of existing calendars have been necessary. In Persia an accumulated discrepancy was disposed of by a reform in 1079 A.D. In the western world the discrepancy had become marked by the sixteenth century and was corrected by Pope Gregory XIII in 1582 by the omission of ten days from that year. For the future the difficulty was to be obviated by the omission of three intercalary days in 400 years. This new Gregorian calendar was adopted but hesitatingly by the Protestant countries—it was not accepted in England until 1752; and the Greek orthodox countries, Russia and Greece, kept the old style until after the Great War. The difference between the Julian and Gregorian calendars amounts now to 13 days. The rules for calendar construction adopted by the orthodox church in a synod in Constantinople in 1923 still differ from those of the Gregorian calendar, chiefly in the location of Easter.

A bothersome confusion was introduced into the calendars of many peoples by the Mohammedan religion. Before the time of Mohammed the Arabs had used a luni-solar year, but in 631 A.D., shortly before his death, Mohammed im-

posed on his followers a lunar year of twelve lunar months of an average of 29 days and forbade the practise of intercalation. This anachronism spread with the Moslem religion over a large part of Africa and the Far East, even into Polynesia. It remains a stumbling block in the way of any international calendar reform.

The Gregorian calendar of the western world has certain irregularities and inconveniences which have become increasingly evident, and with the growth of secularism proposals for reform are heard with increasing frequency. Many projects were advanced throughout the eighteenth century. During the French Revolution an attempt was made to revert to the Egyptian system, with the retention, however, of intercalary days and the division of the month into three ten-day periods. Auguste Comte proposed a year consisting of thirteen months each with 4 weeks of 28 days and one, in intercalary years two, blank days ($364 - 1$ or 2 respectively). Of recent years an increasing pressure for change has come from business groups and social statisticians, who find the irregularities of accepted month intervals a serious obstacle to the achievement of regularity and comparability of records. It is thought by many groups that a fixed calendar with equal time units and the days of the week occurring always on the same date of the month would be far more convenient for a complex commercial organization. But the problem of making any such fundamental change of habits acceptable to the majority of the people of one country or of the world is indeed great. Certain isolated but increasingly numerous industrial groups in the United States, such for instance as Sears, Roebuck and Company, have placed their own business on a thirteen months basis, hoping for an eventual widespread acceptance of the system. In 1923 the League of Nations set up a technical committee to consider calendar reform; this body has gathered suggestions from religious and business groups throughout the world, concentrating attention, however, upon a reform acceptable to western peoples. It has eliminated more drastic proposals for change but has failed to find a generally acceptable solution. Meanwhile, the U. S. S. R. has adopted a five-week calendar combined with a system of rotating holidays for different industrial groups. Whether or not this system will find wide acceptance elsewhere, some form of stabilization of the calendar may perhaps be expected to follow a sufficient widening of the spread of industrial-

ization and mechanization, even though it lag far behind.

CALHOUN, JOHN CALDWELL. (1782-1850), American statesman and social theorist. Calhoun's political career was closely tied up with the economic interests of his state, South Carolina, and of the entire South; his principal significance in American history lies in the cogency with which he framed syllogisms of political theory which rationalized these interests. In the early years of his political career, from 1807 to 1827, until the economic interests of the South and the rest of the country diverged sharply, Calhoun found it possible to be a Whig, a militant nationalist and at times even an advocate of a national bank, internal improvements and a protective tariff. But as the incidence of the tariffs on the South became clear Calhoun shifted his position and in the *South Carolina Exposition* (*Works*, vol. vi, p. 1-87) and his letter to Governor Hamilton (*Works*, vol. vi, p. 144-93) framed the doctrine of nullification. When the drift of events began to indicate that slavery rather than the tariff would divide North and South, Calhoun made explicit the forces making for cleavage and consolidated the theoretical position of the South. He viewed slavery as the foundation of the existence of the South and opposed abolition and all attempts by the North to upset the balance of power in the Senate as striking at the only possible basis on which the Union could continue. The clear cut nature of this position was, in the rapidly shifting political manoeuvres and alignments of the time, a political disadvantage; and though Calhoun held with conspicuous success the posts of senator, vice president, secretary of war and secretary of state he never reached the presidency.

As a political theorist Calhoun ranks among the very greatest that American thought has produced. His political theories are contained in his *Disquisition on Government*, and a *Discourse on the Constitution and Government of the United States* (*Works*, vol. i) and his numerous public utterances. These do not embody a complete theory of the state, but set forth the doctrine of states rights as it came to be accepted in America.

The central concept in his political philosophy is his notion of the "concurrent majority," through which an organism is created to obtain the sense of each interest or portion of the community that may be unequally and injuriously affected by action of the government. The sense of each interest or division thus taken shall be expressed through its appropriate organ and shall be necessary in making or executing the laws or shall constitute a veto on their execution. Thus Calhoun opposed the principle of the numerical majority by a principle which regards interests as well as numbers. According to Calhoun the United States constitution originally established a government of the concurrent majority composed of two elements—the states in their corporate character and their representative population which exercise separate but concurrent action. But the United States government is only part of a system of governments. Each state has its own government, which is its exclusive and representative organ as to all powers which have not been delegated to the United States government. It was to the people of the several states that sovereignty devolved upon the separation from Great Britain, and it was through the exercise of this sovereignty that the state constitutions as well as the United States constitution were created.

Since Calhoun viewed the constitution as a compact between sovereign political communities, he insisted that the individual states enjoy a veto on the proceedings of the government of the United States. The exercise of this negative is possible because sovereignty resides in the people of the several states. It therefore follows that a state may reject, within its own borders, any measure which it deems inconsistent with the terms of the constitution. If three fourths of the states support the action of the United States government, the nullifying state is not bound to acquiesce, but may secede from the Union. The right of secession results necessarily from the nature of a compact between sovereign parties.

Calhoun's work was a powerful attempt to formulate democracy in terms of minority rule.

It failed because it overlooked the growth of the country, in which an identity of interests between its various parts, reconcilable with the principle of majority rule, was already established. The South alone stood outside the influence of economic forces which were welding the West and the older states of the North together. But Calhoun's theory of the concurrent majority profoundly influenced the thinking of many southern statesmen and found practical embodiment in the constitution of the Confederacy.

CALIPHATE. The caliphate is a Mohammedan office or institution involving, theoretically, successorship to the position of the founder of the religion and uniting in a peculiar way functions of church and state. The word *Khalīfah* was used in the Koran in a number of connections, none of which clearly signified succession to the position of Mohammed, and it has since been used by Moslems in various senses besides this central one. Other titles used as more or less synonymous with caliph have been *imām*, referring especially to supreme leadership in worship, and *amīr al-mu'minīn* (commander of the faithful), referring to military authority.

During thirteen centuries of existence the caliphate has met with widely varying fortunes. Its theoretical character, as formulated in Islamic lands and elsewhere, has usually differed widely from actuality. The chief phases of its history include the Medina caliphate, 632 to 661 A.D.; the Omeyyad caliphate at Damascus, 661 to 750; the Abbassid caliphate, 750 to 1258 (at Bagdad regularly from 762); the caliphate under the Mamelukes, 1261 to 1517; and the caliphate under the Ottomans, 1517 to 1924. The apparent continuity of this schedule is deceptive; it suggests a single historical function exercised over all Moslems, whereas after the first phase universality began to disappear. After about 800 A.D. parts of the Moslem world were permanently separated under rival caliphs or

under no caliph, and the theory has been intermittently held in all parts of the Moslem world that the only true caliphs were the first four and that the application of the name to later Moslem rulers was a misuse. Important minor phases are the caliphate of Cordova, the Fatimid caliphate at Cairo and the Shiite and Khawarij schisms.

Mohammed, by combining the traditional limited authority of the sheik among the Arabs with a new absolutism derived from his accepted claim to be the one God's unique spokesman, built up a position in which he acted not only as prophet but as leader in religious worship, chief executive, sole legislator, supreme judge, military commander and treasurer. Advised by a small council of his earliest and most able followers he ruled the life of his community in a unified way, neglecting such distinctions as those between sacred and secular or between religion, government, law, ethics and etiquette.

He died without having made plans for a successor and his followers, stunned by the unexpected event, recognized immediately the desirability of continuing unified headship. A crude form of election, held at an informal meeting of the council and followed by approval on the part of the community, placed the aged Abu Bakr in the position of successor or caliph. Abu Bakr allowed himself to be called only *Khalīfah rasūl Allah* (successor of the apostle of God).

Abu Bakr nominated Omar to succeed him, but the element of election was preserved in that the consent of the Moslem community at Mecca was obtained. Apparently Omar was the guiding mind during both Abu Bakr's and his own period of leadership, and during these twelve years he established the first phase of the institution of the caliphate. The four early caliphs remained regularly at Medina, striving to make all their decisions as Mohammed would have made them and claiming no higher spiritual functions than those of other believers. Extraordinarily rapid conquests carried forward the worldly fortunes of the Moslems. The "prophet's fifth" of all booty as well as of regular revenue after the establishment of conquest was poured into the caliph's hands at Medina and by him distributed to the community. Besides presiding over religious worship and acting as chief executive and judge Omar appointed the commanders of the increasingly large armies, and the governors of provinces far richer than the Arabian home land. After the assassination of Omar, Othman was

chosen by a process resembling Abu Bakr's election, and when he likewise suffered death by violence the Meccan group chose 'Ali, the cousin and son-in-law of Mohammed. The election of 'Ali did not, however, receive unanimous consent. In the civil war which ensued 'Ali was unsuccessful and was slain at Kufa in 661. In later years Shiite Moslems adopted the theory that 'Ali had been the only lawful caliph and that the office was continued by divine appointment to his descendants, rival caliphs being usurpers. The majority of Mohammedans, however, have at all times held that the caliphate passed to Mu'āwiyah and his line at Damascus.

The Omeyyad caliphate at Damascus was a line which became regularly hereditary, since each ruler during his own lifetime designated his successor, usually his eldest son. The principle of election was considered to be maintained in that the caliph procured the consent of his leading subjects to the heir apparent of his appointee. The caliph's function of religious leadership diminished greatly with the rulers of this dynasty and devolved upon a rising group of men learned in the Koran and the traditions of Mohammed. These caliphs lived like exalted sheiks—being personal military leaders and patrons of art and letters, they were easy of access and without Moslem exclusiveness. They carried civil war even to the Holy Cities of Mecca and Medina, where the local Moslems attempted to set up caliphs of their own choosing. The power of this dynasty came to an end partly through personal decline but more from the development of opposition among partisans of the family of 'Ali. With the overthrow of the Omeyyads the shrewder politicians of the family which was descended from 'Abbās, another of Mohammed's uncles, seized the prize of the caliphate.

The new Abbassid caliphs possessed by intermarriage a portion of Persian blood and by association an even larger share of Persian governmental ideas. These caliphs, established after 762 in the new city of Bagdad, were served with the pomp and submissiveness to which the former Persian emperors had been accustomed. Apparently very religious, they nevertheless increasingly employed learned advisers to adapt the sacred law to their desire. Actually their religious leadership was almost entirely formal and their effective duties chiefly administrative. The Moslem church (if such a word with its Christian associations can, without too much confusion, be applied to the total Mohammedan religious institution) had become nearly self-

sufficient in its mosques, with their *imāms* and their '*ulama*, or learned men, who knew the *shar'*, or sacred law. *Qudāt*, or judges, and *muf-tūn*, or counselors, were selected from those versed in the law to aid the secular authorities on the side of justice. Their power was very great in all Moslem lands down to the nineteenth century, since in theory legislation had ceased with Mohammed and those who interpreted his law and adapted it to the conditions of the time were exercising a portion of his authority. In fact, by applying the Koranic principles to new circumstances and by codifying the legislation scattered through the Koran as well as the traditions and the decisions of judges, the Moslem learned men exercised in a concealed and limited way an actual function of legislation. Even to the present in most Moslem lands the laws of marriage and inheritance remain as developed a thousand years ago and are applied by judges trained in an undifferentiated body of theology and law. In this legislative process the caliph had no recognized part.

Within less than a hundred years from the establishment of this dynasty its secular power began to be taken over by individuals or lines drawn from 'Turks, Persians, Kurds, etc. Considerable wealth, splendor and dignity remained to the caliphs but their authority became slight in both church and state. For the *amīr al-umara*, commander-in-chief, ruling at Bagdad or warring in various provinces, the constant existence of a powerless caliph was a legal support and a cover of authority. For Moslem secular rulers as far west as Morocco and as far east as India the caliph was likewise a bestower of lawful authority, since diplomas of investiture, granted by him in exchange for costly gifts, confirmed such rulers in their place and power. The caliphs thus possessed without effort the right to invest secular rulers with office, a right which the great mediaeval popes strove in vain to establish for their successors.

In the eleventh century A.D., when the caliph's actual authority had been very much reduced, apparently sincere theorists set up for him most extensive claims as the "source of all authority and power in the Moslem world." He was in the view of many the sole representative on earth of the power of God, entitled to command the unreasoning obedience of all believers. Noteworthy among these legists was Mawardi, who affirmed as qualifications to be required in a caliph: membership in the tribe of the Quraysh (the Prophet's kin), male sex,

full age, good character, freedom from physical and mental defects, comprehensive legal knowledge, administrative ability and courage and energy in the defense of Moslem territory. Mawardi stated as the functions of the caliph: the defense and maintenance of religion, the decision of legal disputes, the protection of the territory of Islam, the punishment of wrongdoers, the provision of troops for guarding frontiers, the waging of holy war against those who refused to accept Islam or to submit to Moslem rule, the organization and collection of taxes, the payment of salaries, the administration of public funds, the appointment of competent officials and personal attention to the details of government. A glance at this list of functions shows them to be not at all spiritual and only in the first and second items what might be called religious or ecclesiastical. The description is almost entirely that of an ideal secular ruler. Strangely enough the contemporary writer Alberuni affirms, more realistically for his time, the opposite view that the caliph controlled only matters which concerned religion and dogma and that he had no authority in the affairs of this world. The fact appears to be that the actual position of the caliph was from the middle of the thirteenth century ordinarily of very small consequence, but that as in the case of the emperor of the Holy Roman Empire men saw around him the vast shadowy outline of past greatness, which assumed different aspects according to the mentality of the observer. In later centuries both theorists and practical men continued to see the caliphate as very great, but with shifting and often intangible content. Nevertheless, it was granted, an individual caliph could be deposed by action of the believers, supported by a *fatwa* or decision of a *mufiti*, if proved to have violated an essential point of the sacred law.

After the Mongols captured Bagdad in 1258 and exterminated all members of the Abbassid family upon whom they could lay hands, the Mameluke sultans in Egypt took advantage of an exceptional opportunity to obtain sanction for their power by maintaining in Cairo a real or pretended descendant of Abbas. These caliphs claimed wide jurisdiction and vast authority, but exercised no more real power than had the later Bagdad caliphs. Some of the fifteen were very poor but at the proper times they installed the Mameluke sultans with great pomp and ceremony. Their position in the eyes of the remainder of the world was greatly reduced, and it was during this time that the great fourteenth

century legist, Ibn Khaldūn, wrote that the caliph, once a secular ruler, later a religious leader, had become but a name. The last of these caliphs was captured by Sultan Salīm I of Turkey and kept in Constantinople from 1517 to 1523. Sulaymān appears to have sent him back to Cairo, where he lived from 1523 until his death in 1543, continuing to style himself caliph.

There have been at least two erroneous conceptions of large import which have prevailed until recently in the western world, and to some extent even in the Mohammedan world, as regards the Ottoman caliphate. The first of these is that Sultan Salīm I bought the title of caliph from the last Abbassid at Cairo, or had it left to his house by will, so that from about the year 1517 the Ottoman chiefs were both sultan and caliph. The second misconception is that the office of Ottoman caliph was very similar to that of pope by reason of its supreme spiritual authority over all members of a numerous and widely spread religious organization.

Recent investigations have shown that some of Salīm's predecessors used the title caliph as regards themselves and were so addressed by other Moslems, the word having a limited meaning which might perhaps be compared to the complimentary use of the word caesar. It appears also that Salīm I and his son the great Sulaymān avoided apparently with care the use of the word caliph. Ottoman legists of their time inclined to the view that the caliphate had lasted only thirty years until the death of 'Alī. The first diplomatic document known which applies the words caliph and *imām* to the Ottoman sultan is the Treaty of Kuchuk Kainarjī with Russia in 1774.

At this time the erroneous comparison of the caliph's position with that of the pope began to receive general acceptance in both the East and the West. It has been pointed out that of the powers exercised by the pope (performing mass, forgiving sins, promulgating dogma, judging finally the dogma and the liturgy, canonizing saints, granting indulgences and acting as supreme judge in certain cases) no trace can be found in the caliphate; nor was the caliph ever held to be the depository of divine truth. The sole valid point of comparison lay in the claim, revived from earlier centuries, to the undivided allegiance of a great religious community. To the extent that the caliph functioned at all he seems to have been an official much closer in character to the imperial than to the papal status.

In the course of the nineteenth century the

Ottoman Turks came to believe in the theory of the universal authority of their sultan as caliph. The constitution of 1876 proclaimed that "the sublime Ottoman sultanate, which possesses the supreme Islamic caliphate, will appertain to the eldest of the descendants of the house." Sultan 'Abdul-Hamid II made use of this theory to stir up sympathy in many Mohammedan lands; the construction of the Hedjaz railway to facilitate the Meccan pilgrimage was in part an outcome of this theory, in which some force remained as late as 1923, when the Moslems of India expressed their interest in the caliph at Constantinople. But the post-war government of Turkey, having previously canceled the sultanate, acted in conformity with fact when in March, 1924, after a fifteen months' trial during which 'Abdul-Majid II sought to perpetuate his office as a sort of papacy but could discover no real duties to perform, it abolished the office of caliph.

King Husayn of the Hedjaz made an attempt to appropriate the title, for which there seemed to be no demand, and according to some affirmations British officials or individuals lent him encouragement. However that may be, the speedy loss of his temporal authority and his departure from the Holy Cities in 1925 put an end to his dream. Here and there hints have been dropped to the effect that King Fu'ad, as head of the largest Moslem state claiming independence, might well be made caliph. Fu'ad's Albanian descent and westernization, however, make this idea absurd. The suggestion has also been made that King Ibn Su'ud of the Hedjaz and Nejd, an independent Arab and actual ruler of the Holy Cities, is the logical candidate. Ibn Su'ud seems, however, to have no desire to assume the title. The word is still used by certain lesser officials in the modern world, such as the sultan of Morocco and some chiefs in Java, but inasmuch as these personages are neither independent nor of the tribe of the Quraysh they clearly can claim no universal authority.

The deposition and exile from Turkey of the Ottoman caliph do not in legal theory affect the existence of the office, which theoretically awaits a new incumbent. Indeed some Moslems have maintained that the Turks were but showing proper respect to the office by turning out of it a man and a dynasty unable longer to fulfil the task of defending the faithful. While a few Indian Moslems (Aga Khān and Amīr 'Alī) protested the deposition of Islam's "spiritual leader," most non-Turks, if not coldly indifferent, accepted the deposition and concentrated

on the task of finding a new incumbent for the office. A conference was held at Cairo in May, 1926, in which the qualities of the caliph were reaffirmed in a form not unlike that of Mawardi with particular emphasis upon descent from the Quraysh and political independence. But no candidate could be presented who possessed the necessary qualifications, and the conference proved inconclusive.

Similarly the proposals of "regionalists" favoring local caliphs, of "reformers" favoring an all-Islamic council with a caliph as its executive and of the Indian Caliphate Committee, which formerly supported 'Abdul-Majid but latterly has leaned toward Ibn Su'ud, have all come to nothing. Although the important book by 'Abdul-Raziq, *Al Islam wa usul al-hukm* (Islam and the foundations of sovereignty, Cairo 1925), was condemned by the Cairo conference for its denial of the obligatory character of the caliphate, the Mohammedan world seems as a whole to have accepted the view that the caliph is nothing if not the secular head of the Moslem community and that since no Moslem ruler can pretend to wield authority commensurate with the caliph's duties the institution is for the present defunct.

An interesting question arises as to the extent to which such movements as pan-Islamism, pan-Arabism and pan-Turanism can take the place of the religious unity formerly symbolized by the caliphate. While all these include chiefly peoples of the Mohammedan religion they look toward monarchies or federations of a purely secular character. 'Abdul-Hamid II was somewhat interested in the notion of pan-Islamism, but the thought of uniting under one government all the Moslems of the world, spread from Morocco to the Philippines and from central Africa to southern Russia and western China, does not belong in practical politics. Pan-Arabism is scarcely more possible when Moslems speaking the Arabic language are ruled in such diverse ways as in French North Africa, Egypt, Syria, Iraq and the divisions of Arabia. There is also a small but intelligent and active minority of Christians and of Jews who speak Arabic as their primary language and who have therefore a place in pan-Arabism. The pan-Turanians are similarly under very diverse governments, in Turkey, in several republics of Soviet Russia, in China and perhaps among the Mohammedans of India. The people which showed for a time some enthusiasm in this cause, the independent and progressive Ottoman Turks, have set their

faces firmly toward the West. None of these movements therefore seems destined to replace the caliphate as a unifying idea for Islam.

The caliphate is gone and may never be revived. Nevertheless there is a growing feeling of unity within Islam which perhaps descends in a direct line through the generations of learned men, from those who first began in the time of the Omeyyads to take over the religious leadership for which the caliphs of that dynasty were not temperamentally qualified. The world wide improvement in means of communication and the extension of the use of printing have operated among Mohammedans to increase physical contact and have enabled them to realize the possibilities of religious cooperation. The annual pilgrimage exists actively for bringing together Moslems from all quarters. True, there are among Mohammedans extreme ranges of opinion, from conservatives in dogma like the 'Ulama of Egypt and conservatives in practise like the Wahhabis of Nejd to extreme liberals in practise like the ruling group in Turkey and liberals in doctrine like the Ahmadiyyah of India. Complete organic unity in Islam is at least as impracticable as unified church organization would be within Christianity. But further unification of feeling and perhaps increase of organization seem likely to take place without a serious attempt to reestablish a personal center in a restored caliphate, at least for a long time to come.

CALL MONEY is the term applied to funds which are loaned on demand in the open market. It is used by domestic banks as secondary reserves, by foreign banks for the employment of international balances and by corporations for the investment of surplus cash. It is borrowed by brokers and dealers to finance their operations. To a lender call money represents an outlet for the productive employment of temporarily idle funds without sacrifice of their availability for other uses; to a borrower, an opportunity to adjust his indebtedness to daily fluctuations in his need for funds. The largest market for call money in the world is in New York City, where brokers in securities on the stock exchanges are accustomed to finance a large proportion of their dealings through call loans. Smaller call markets of a similar character are found in other financial centers, notably Boston and Chicago, London and Berlin. There is a small market for call money based on acceptances in New York but the principal use of call money by bill brokers occurs in London, where dealings in acceptances form the framework for the short term open money market.

There are three major requirements for a true call money market: the availability of readily marketable collateral as security for call loans; a broad open market to insure their liquidity; and day to day fluctuations in the demand for funds on the part of both borrowers and lenders. Funds on call must be readily available to lenders when they are needed elsewhere. Call money markets, therefore, have developed around securities and acceptances as collateral, both of which can be instantly disposed of, when necessary, in organized markets. The relationship between lenders and borrowers of call money, furthermore, must be impersonal. Call loans do not include demand loans made in the course of established customer relationships. These latter loans are common throughout the

banking system of the United States but are not in fact callable on demand since the convenience of the customer, his ability to finance himself elsewhere and his value as a future client must be considered before a loan is called. A broad open market is also necessary for the borrower to have reasonable assurance that he will be able to transfer his loans to new lenders when they are called. For these reasons call money markets are of necessity confined to the larger money centers. The underlying transactions may take place elsewhere but the actual conclusion of the loan must be in central organized money markets, such as New York and London, that are broad in character, impersonal in their relationships.

There must also be a genuine need for day to day loans. There is no accident in the fact that call money is dealt in more extensively in New York than in London. The American commercial banking system consists of thousands of independent unit banks with the consequence that clearing operations between banks are large and are reflected in a rapid shifting of balances from bank to bank. It is a part of the American banking tradition, therefore, for banks to invest a large proportion of their funds in liquid interest bearing assets, such as call loans, that can be converted into cash at short notice. The basis of the demand for call loans from brokers rests on the widespread American custom of carrying securities on margin. Since the bulk of the transactions in the New York security markets is settled on a daily basis, individual brokers have wide day to day fluctuations in their demand for funds.

Practically all call loans in New York are made by, or through the agency of, large banks which are close to the market and in a position to scrutinize and safeguard the collateral. Formerly the call market depended largely on direct loans from these banks, but in recent years it has drawn a great volume of funds from interior banks and from other sources such as corporations and foreign banks. On October 1, 1929, call loans in New York amounted to nearly \$8,000,000,000, more than half of which was loaned by others than domestic banks. After the market collapse of 1929 loans from domestic banks again became the chief factor in the supply of call loans. The call market has always been attractive to correspondent banks in New York because they hold large deposit balances from interior banks, which are particularly subject to immediate withdrawal. Prior to the establish-

ment of the Federal Reserve system pressure on the call market was extreme when these deposits were withdrawn, and on occasions when heavy interior withdrawals coincided with an unfavorable gold position call loans became frozen and helped to precipitate a financial crisis.

Day to day fluctuations in call rates are frequently wide and apparently erratic, but the average renewal rate on call loans on a monthly basis is more sensitive than any other money market rate to changes in credit conditions. Any change in the supply of readily available funds is quickly reflected in a flow of funds into or out of the call market, where rates are depressed or raised as the supply becomes adjusted to the demand. Periods of easy credit conditions, therefore, are characterized by a fall in call rates to among the lowest in the money market, and periods of credit stringency by a rapid rise to a position above other rates. Under normal circumstances call rates have found a level close to, but slightly above, the discount rate of the Federal Reserve Bank of New York and below quotations on prime open market commercial paper. These fluctuations are of particular concern to operators in the security markets, partly as an element in the cost of carrying on their transactions and an index of the availability of credit for future operations, but also because they indicate the trend of underlying credit conditions.

Two rates are quoted on call loans at the present time, a renewal rate and a rate for new loans. The new loan rate is the quotation applying to the most recent loan made on the floor of the stock exchange and often fluctuates hourly in response to changes in the supply and demand for funds. To prevent fluctuations in this rate from affecting rates on the whole body of loans a renewal rate is agreed upon daily which is not compulsory but customarily applies to all loans holding over from the preceding day.

CALLENDER, GUY STEVENS (1865-1915), American economic historian. His chief contributions are contained in the series of intro-

ductory essays which form part of a volume of readings which he edited—*Selections from the Economic History of the United States, 1765–1860* (New York 1909).

He is probably best known for his emphasis on internal improvements as the central theme in American economic development. Accordingly he stressed the building of railroads as a phenomenon of far greater importance than the establishment of textile mills on the eastern seaboard. This attempt at synthesis, however, discloses his weaknesses: his tendency to see things too schematically and to seek simple explanations of complicated series of events, his readiness to ignore institutions not primarily economic and his failure to appreciate the role of ideas in economic development.

The freshness of his approach is more clearly evidenced in stray bits of interpretation and in the questions he asked. Callender saw, for example, that the American labor problem was not the English labor problem transplanted to a new world. Accordingly he looked upon trade unions in early American history as foreign ideas and devices which an enthusiastic people at a time of great social and moral ferment attempted to apply to a "society almost completely free from the ills those devices were designed to cure in Europe." He observed also that the American has turned a large part of his energies into the production of wealth. He wondered why the Anglo-Saxon has developed differently in the United States than in other new countries such as Canada and Australia. He raised a host of questions about the effects of slavery on the North as well as on the South and the reason for its spread in the United States at the very time it was dying out elsewhere. It was this type of question which showed his originality, his interest in the non-European quality of American problems and at the same time his ability to think of America as part of a larger whole.

HELEN R. WRIGHT

CALVERT FAMILY, English colonial administrators. The members of the Calvert family, George (c. 1580–1632) and his two sons, Cecilius (1605–75) and Leonard (c. 1610/11–47), projected the province of Maryland in 1632 and directed its affairs until 1675. George Calvert prepared himself for public life by an Oxford education, a "grand tour" and service as private secretary to Sir Robert Cecil while that statesman was directing the policy of King James. He gained years of experience as legislator in the

House of Commons, and as administrator and diplomatist from six years of service as a principal secretary of state. In the face of pending measures for the persecution of the Catholics he became a convert to their faith and resigned the secretaryship. His remaining years, 1625–32, were devoted almost wholly to efforts to found a colony in the New World. Soil and climate defeated him in Newfoundland, where he had planted a colony in 1620 and labored with it until 1629. Protestant opposition confronted him on the south Atlantic coast, but shortly before his death he received the assent of King Charles to the grant of the province of Maryland on terms that revived in his son Cecilius the powers of a great feudal lord and at the same time guaranteed civil rights to the colonists. Cecilius Calvert, who, like his father, was a capable administrator, remained in England to promote emigration to his province and to protect it from Catholic as well as Protestant foes. His brother Leonard administered the government in Maryland under his direction, and while he lacked some of the qualities of leadership he was often discreet and always faithful to his trust. Although both brothers were Catholics, no measures were ever adopted to make Maryland solely an asylum for the persecuted of that faith. Protestants were always welcome, and from the very beginning Cecilius insisted that Catholics give no offense to Protestants. When this policy had been successfully pursued for fifteen years it was embodied in the Toleration Act, which was passed by the Maryland Assembly, April 21, 1649. Until 1638 Cecilius insisted on retaining the sole right to initiate legislation, but in that year his brother persuaded him to yield, and this was the first step in an orderly development of democracy in one of the best governed of the English colonies in America.

CALVIN, JEAN (1509–64), leader of the Protestant Reformation in Geneva. He was primarily a theologian and his social thought is

in the main a by-product of his religious ideas. Calvin's Protestantism, although thoroughgoing, was differentiated from that of Luther both by his conception of God as the absolute sovereign who while infinitely removed from a wholly sinful world had yet created its every detail for the increase of His glory and by the doctrine of predestination in its most drastic form of the double decree. This theology, while it insisted on salvation by grace not works, shut out mystical contemplation and drove the believer into an active, strenuous life directed toward the realization of Christian ideals of conduct. Calvin's objective conception of religious truth precluded toleration and caused him to retain the ideal of the universal church to which even the unregenerate must be made to conform. The combination of these elements led to the church discipline of Geneva.

From his hypothesis of the immediate dependence of all worldly events on God's will Calvin derived his doctrine of the divine ordination of the principal institutions of society—church, state, property, family. He was thus a strong upholder of authority. The state is co-ordinate with the church in promoting God's kingdom on earth; the two have a common purpose but different spheres of influence. Underneath his conservative authoritarianism, however, lay a revolutionary principle which after his death was to become of great importance: although a strong defender of passive resistance he conceded that in extreme cases obedience to God's will was an obligation transcending all other duties and abrogating all other allegiances.

The general tenor of Calvin's own system in Geneva was an authoritarian Christian socialism strictly subordinating individuals to the one great aim of increasing the glory of God. But later developments of Calvinism, by bringing out its latent anti-authoritarian tendencies, favored a democratic individualism, tinged, however, as a consequence of the doctrine of predestination, with a conservative anti-equalitarianism. During Calvin's lifetime the civil government in the city-state of Geneva, as represented by the Civil Council, was nothing more than a subordinate body, a coercive agency, for enforcing on the community the strict church discipline promulgated by Calvin and the ecclesiastical committee known as the Consistory. The policy of complete separation of church and state which was later forced upon Calvinism was the result not of any recognition on its part of

relativity in religious truth but of the fear of political interference by a more powerful civil authority.

Calvinism, which at the outset found its greatest support in urban centers, was the first of the Reformation movements to recognize the existence of a new economic society characterized by the commercial rather than the mediaeval agrarian viewpoint. Calvin's justification of moderate interest, which hitherto church moralists had condemned, reveals him as among the first to understand the productive functions of capital. Rejecting monasticism Calvin dignified ordinary economic activities by designating them as "callings," as tasks set directly by God. For hedonistic motives to labor he substituted the glory of God and the general good; the economic virtues of thrift and industry he identified with the moral virtues. In no sense did he encourage moral laxity in economic relations. On the contrary, he tried to moralize as never before all phases of social life.

The very rigor of its standards made Calvinism a constructive rather than a hindering force in modern economic development. The idea of "calling" reinforced by the psychological effect of the doctrine of predestination gave a religious sanction to the most strenuous, rational, systematic labor for impersonal ends. Labor thus became a means of serving God and of proving one's own state of grace through ascetic self-discipline. Slothfulness became the deadliest of sins and fear of self-indulgence made the Calvinist a small consumer and a large saver. In Geneva this resulted in an extraordinary system of church discipline, but with the change of emphasis from church to self-discipline it later powerfully furthered the development of individual capitalistic acquisition, especially after worldly success came to be recognized as a token of grace.

CALVINISM. See PROTESTANTISM.

CALVO, CARLOS (1824-1906), Argentine diplomat, historian and publicist. Calvo's diplomatic achievements were many. He assisted in settling the differences between Buenos Aires and the other Argentine provinces; he helped to bring about an agreement between Paraguay and Great Britain on the Cronstatt question; he played an important part in the famous *Alabama* arbitration; and he made significant contributions to the work of the Congress of Berlin. But the great reputation which he achieved at home and abroad was the result rather of his prodigious labors as historian and publicist.

Calvo's work exhibits a practical historical positivism rather than analytic strength, and it has been said that he is often no more than a compiler. As a historian he is certainly to be classed as a chronicler. But he greatly influenced the development of international law and widened its orbit immensely. He came to represent in international law the Latin American tradition and aspirations. His importance in this connection is obvious from his enunciation of the Calvo Doctrine against the forcible collection of private debts. In general he stood for the principles of arbitration and non-intervention in Latin American affairs. The progressive editions of his classic treatise indicate its increasing scope. His voluminous collection of treaties has taken rank with Dumont's and Marten's, and was largely intended to provide a body of material which might aid in the settlement of Latin American disputes concerning boundaries. Calvo's services to Latin America were formally recognized by the third Pan-American conference, which met at Rio de Janeiro shortly after his death.

Calvo was much influenced by the work of Henry Wheaton, who had brought American claims to international attention after the Revolutionary War, particularly as they related to the rights of maritime commerce. The analogous

role of Calvo is evident. He translated Wheaton's *History of the Law of Nations* and through him derived his own historical positivism. It is strange that both these champions of the emerging but hardly established rules of international law should have based their work theoretically upon positivism and attributed so much weight to the "actual usages" of the law of nations.

CALVO AND DRAGO DOCTRINES. During the nineteenth century the countries of Latin America were frequently subject to pecuniary claims on the part of foreigners. These claims were based upon injuries received during civil wars, acts of violence, such as false arrest or imprisonment and expulsion, or breach of contracts concluded with the governments. While requiring and seeking foreign investments and immigration the Latin American countries sought to maintain the usual prerogatives of sovereignty; thus they endeavored to find a legal means of preventing the too frequent diplomatic interposition of foreign governments in behalf of their citizens and to deny to foreigners the advantageous status which they had been deemed to enjoy. These efforts were expressed in constitutions, statutes, treaties (where obtainable) and in contracts concluded with foreigners. These instruments all look to the propositions that the foreigner is bound by the local law, that he cannot make claim for injuries arising out of civil war or mob violence under conditions not available to nationals, that in his private litigation he must exhaust his local remedies and establish a "denial of justice" before invoking diplomatic protection, and that in his litigation with the government arising out of concession

contracts or franchises he must make the local courts his final forum. Where the system of political administration is such that political outbreaks, disturbances and arbitrary violence are merely spasmodic and fortuitous events and the government is not chargeable with negligence and where the system of judicial administration is such that notorious perversions of justice are exceptional and rare, it may be said that these principles, apart from foreclosing interposition in the event of denial of justice, approximate the prevailing rules of international law.

The whole doctrine of the final jurisdiction of the local courts over the complaints of aliens, with a denial of the privilege of diplomatic recourse, has been called the Calvo Doctrine after a celebrated Argentine jurist who enunciated these views as early as 1868. Calvo maintained that apart from treaty it was contrary to fundamental principles of international law to give foreigners in some countries a more favored position than in others, and that it was an abuse of physical power for stronger states to exact pecuniary indemnity from a weaker state under circumstances which would not allow them to make such claims upon each other. The Calvo Doctrine has in application been commonly restricted to concession contracts concluded between the government and an alien and in this sense has received the name "Calvo clause"; it provides (either in constitutions, statutes or the contract itself) that the foreigner "renounces all right to prefer a diplomatic claim in regard to rights and obligations derived from the contract" or else that "all doubts and disputes" arising under it "shall be submitted to the local courts without right to claim [the] diplomatic interposition" of the alien's government.

As a general rule, a government does not interpose, except by the use of good offices, to bring about the execution of contracts voluntarily concluded by its citizens abroad unless there be established a denial of justice in the foreign courts. Thus interpreted the Calvo clause would be merely confirmatory of international law and unobjectionable. But at times it has been maintained by Latin American countries that the committal to resort to the local courts exclusively and to forego diplomatic protection is without exception or qualification, especially when the committal is given in return for a favor or concession by which the foreigner agrees to consider himself, for the purposes of the concession, a citizen of the local country and

to waive his rights as a foreigner, including the right to invoke diplomatic protection. This position, though it has its merits, is not admitted by the United States or by most European countries.

The position of the United States is perhaps best expressed in an instruction of Secretary of State Bayard in 1888: "This government cannot admit that its citizens can, merely by making contracts with foreign powers, or by other methods not amounting to an act of expatriation or a deliberate abandonment of American citizenship, destroy their dependence upon it or its obligations to protect them in case of a denial of justice" (Mr. Bayard, Sec'y of State, to Mr. Buck, Minister to Peru, Feb. 15, 1888, Moore's *Digest*, vi, § 918). Secretary of State Gresham, in interpreting in 1893 a Calvo clause in the Venezuelan constitution, took the position, which the latest arbitral decisions have supported, that the stipulation to resort to local remedies must be carried out, but that it will not excuse a denial of justice—a wrong which would still justify diplomatic interposition (Moore's *Digest*, vi, § 918). This question was submitted to the governments by the preparatory committee of jurists which laid the ground for the Hague Codification Conference of 1930. The replies of the governments (League of Nations, Conference for the Codification of International Law, *Bases of Discussion . . . Drawn up by the Preparatory Committee*, vol. iii, p. 133-35 and supplement) for the most part sustained the views expressed by secretaries Bayard and Gresham, as does Basis of Discussion No. 26 proposed by the Committee of Jurists, a proposition which, however, was not reached for discussion prior to the adjournment of the conference.

There have been twenty-one notable cases involving the validity of the Calvo clause which have come before international tribunals, and in which exhaustive opinions have been written. Ten of these, including the two latest, uphold the binding character of the stipulation to resort to the local courts, whereas eleven have denied the validity of the stipulation. In the main, the latter rest on one or other of the following grounds: that it is beyond the competence of an individual to contract away the superior right of his government to protect him [*Rudloff* (U. S.) *v. Venezuela*, Ralston 819-41 (1903); *Martini* (Italy) *v. Venezuela*, Ralston 183, 187 (1903)]; that where the government had annulled the contract without first appealing to the local

courts such action relieved the claimant from the stipulation not to make the contract the subject of international claim [Milligan (U. S.) v. Peru, Moore's Arb. 1643 (1868); North and South Amer. Const. Co. (U. S.) v. Chile, Moore's Arb. 2318-22 (1892)]; that the claim arose not out of the contract itself, but out of some violation of property right, and is based on tort [Selwyn (Gr. Brit.) v. Venezuela, Ralston 322, 323 (1903); Rudloff v. Venezuela, *supra*].

In the two most recent cases, before the United States-Mexican Commission under the treaty of 1923 and the British-Mexican Commission of 1926, it has been held that the clause made it essential for the foreigner to resort to his local remedies in the first instance and that until he did so he had no standing before an international commission, and this notwithstanding the fact that in certain articles of the treaties of 1923 and 1926, under which the commissions were established, the usual requirement of exhausting local remedies was dispensed with as a condition of the admissibility of a claim [North Amer. Dredging Co. of Texas (U. S.) v. Mexico, 20 A.J.I.L. 800 (1926); Mexican Union Railway, Ltd. (Gr. Brit.) v. Mexico, 24 A.J.I.L. 388, 394 (1930)]. This interpretation indicates that the effect given to the clause is to emphasize the usual requirement of international law that local remedies must be exhausted (thus canceling in these cases the waiver of the treaty) and that a claim may be admitted only when, after such practical exhaustion, a denial of justice can be established. As thus interpreted the clause represents merely a well established rule of international law, and its utility lies mainly in that it enables the defendant country to rely upon an express stipulation when it insists that local remedies must be employed.

The joint intervention of Great Britain, Italy and Germany against Venezuela in 1902 on the erroneously supposed ground that they were seeking merely to collect unpaid bonds held by their citizens led Luis Drago, minister of foreign affairs of Argentina in 1902, to submit a note to the United States Department of State proposing a policy, intended to be a corollary of the Monroe Doctrine, that "the public debt [of an American state] can not occasion armed intervention nor even the actual occupation of the territory of American nations by a European power" (U. S. For. Rel. 1903, p. 1-5). Drago's protest lay solely against the use of armed force in the collection of public debts and was not directed against diplomatic interposition in

general. He also added that he did not intend to make his doctrine a defense "for bad faith, disorder, and deliberate and voluntary insolvency." Drago argued that the purchaser of a foreign bond buys with open eyes and in the price paid takes account of the value of the security, the credit of the debtor government and all the other factors which enter into the bargain. He added that the emission of the loan and bond is an act of "sovereignty," that the creditor knows that payment may be refused or the debt reduced by similar act, that the usual civil remedies are barred and that the state is the sole judge of its ability to pay. He maintained that it is unfair to the people of both states to make this voluntary contract the subject of armed political action involving whole nations and to make the government, in effect, the guarantor of its citizens' bonded investment.

The Drago Doctrine is thus narrower than the Calvo Doctrine, for it relates only to public bonds and decries only armed intervention. There has been a difference of view among European powers and publicists as to the propriety of intervention to collect public debts, though armed force has rarely been used except in cases of bad faith or fraud. The preponderant view is that intervention is not warranted in the event of an honest inability of a state to pay its debts, but only when, with means at hand, there is a wilful refusal to pay; or when foreign creditors are illegally treated, especially if they are discriminated against in favor of national creditors; or if improper preferences are given; or when special funds assigned as security for the debt are arbitrarily diverted to another purpose: in short, when bad faith may be considered the moving cause of the default. Despite this disagreement as to a formal rule, to the extent that law is deducible from practice it may be said that armed intervention is not sanctioned except in cases of bad faith, and even in such cases it has been extremely rare. The Venezuelan interventions had as their foundation a persistent refusal of Venezuela to settle tort claims, and the bonds were drawn in only collaterally and incidentally. The Drago Doctrine is mainly of interest because it calls attention to the political danger and the undesirability of armed intervention on behalf of private claimants of all kinds, not because the evil which Drago feared was particularly notorious.

The Drago note had the effect of inducing the United States to place on the agenda of the Third American Conference of American States

at Rio de Janeiro in 1906 and of the Hague Conference of 1907 the consideration of the question of national policy in the pursuit of contract claims. Although it had not been the policy of the United States or of other countries generally to use force to collect contract claims, distinctions between "fraud and wrong-doing or violation of treaties" and "simple non-performance of a contract with a private person" engaged major attention, with the result that the use of force, while deprecated in the latter case, was implicitly and conditionally approved in the former. At The Hague General Horace Porter, for the United States, proposed that the use of force for the collection of contract debts is not permissible until after the justice and amount of the debt, as well as the time and manner of payment, shall have been determined by arbitration. After several amendments, a convention was voted by thirty-nine states, making the use of force conditional upon (1) a refusal by the debtor state to arbitrate; or (2) obstruction by the debtor state of the formulation of a *compromis* after arbitration is accepted; or (3) failure to carry out an award. Perhaps these terms are more definite than "bad faith," or "deliberate and voluntary insolvency." Seven Latin American states made reservations in line with the Venezuelan objection to the convention, to the effect that arbitration should be permitted only in case of a denial of justice after judicial remedies have been exhausted—a proposition entirely sound, for when the debt is not denied arbitration has no purpose. Drago made a reservation on behalf of Argentina, in which he was joined by seven states, that "public loans with bond issues constituting the national debt cannot in any case give rise to military aggression nor to the occupation of the soil of American states."

The Porter Proposition is at once narrower and wider in scope than the Drago Doctrine. In that it actually sanctions the use of armed force in a type of situation in which the United States and most other powers have, as a matter of policy, declined armed intervention, the Porter Proposition is narrower than the Drago Doctrine, which would deny absolutely the use of force, at least in the collection of public bonds. As a definite check upon the use of force in first instance and a public profession of faith in arbitration, it is to be welcomed, for pacific blockades, threats of hostilities and rumors of warlike preparations have a disturbing effect on peace and commerce. The Porter Proposition is wider

in scope than the Drago Doctrine in that it applies to all contractual debts and not merely to public bonds. Yet doubts may easily arise as to the meaning of "contractual debts." Bond debts, while not usually presented for payment through diplomatic procedure, have occasionally been submitted to international tribunals, which have generally denied their jurisdiction over them in the absence of express words submitting bond claims for determination.

While thus far neither the Drago Doctrine nor the Porter Proposition has been applied in actual cases which have reached public notice, they may well have been effective in restraining official action, and they have served to call attention to the tendency, too prevalent in the nineteenth century, to use political means to enforce pecuniary legal claims. In limiting the use of such means they constitute part of the movement of the twentieth century either to exert more patience in the diplomatic settlement of such questions or, if unsuccessful, to submit them more readily to international arbitral (judicial) decision. In this respect there is no reason to segregate contract claims, for this sensible means of settlement should be extended to all pecuniary claims. While obligatory arbitration of all such cases is not yet achieved, the tendency is not to resist the movement too strongly. It is still true, however, that those economic conflicts of interest among the nations which are too profound and persistent to be formulated into legal issues or disputes are likely to be more prevalent than ever; and for the adjustment and conciliation of these little if any machinery is available.

CAMBACÉRÈS, JEAN JACQUES RÉGIS DE (1753-1824), French statesman and jurist. He was born at Montpellier of a family of the *noblesse de robe*. He was successively deputy to the National Convention, member of the Council of Five Hundred, second consul under Napoleon and arch-chancellor of the empire. As a member of the Committee of Public Safety he was interested in legislation and in June, 1793, issued several reports, one of which sought to give natural children the same rights as legitimate ones, while another dealt with adoption. He proposed the jury as a legal institution to deal with civil affairs and drew up two projects for a civil code (August, 1793, and 'Thermidor, year II). In line with the ideas of his day his projects sacrificed individual and family rights to a despotic state which was founded on equality, which looked to the destruction of parental authority and to the crumbling of patrimonies and which sanctioned the retroactivity of laws. In the Council of Five Hundred he proposed still another plan which was, however, very much milder and made no further progress. In 'Thermidor, year VIII, he was reinstated on the commission for drawing up a civil code but when his projects were rejected as "contrary to natural equity" he himself abandoned them. He is regarded as the principal author of the Code Civil completed in 1804, although his work on this was in a spirit entirely at variance with his former views, especially as regards the inheritance of property. He resumed his duties during the Hundred Days, was exiled as a regicide in 1816, pardoned by the king and made a duke in 1818.

CAMBON, PIERRE JOSEPH (1756-1820), French statesman and financier. As a member of the committee of finance first of the Legislative Assembly and later of the National Convention Cambon practically administered French finances between October, 1791, and April, 1795. Essentially an honest, accurate accountant, he possessed some of the qualities of a great minister of finance. At the cost of popularity he vigorously opposed the expenditures and demands of the revolutionary committees, the

spoliation of precious metals from the churches and the abuses in the administration of taxes. In contrast to the steadfastness with which he tried to prevent corruption and waste, Cambon's policy with regard to the assignats was inconsistent and shifting. He was indeed thoroughly aware of the dangers inherent in the excessive issue of paper money and at times did everything in his power to regulate and reduce it. But at other times, as in his reports of April 17-19, 1792, and of February 1, 1793, when he was carried away by his interest in the prosecution of war, he not only sponsored but eagerly urged new issues.

Cambon is best known for his work in connection with the public debt. His famous *Rapport sur la dette publique*, which the Convention accepted on August 24, 1793, provided for the creation of the *Grand Livre*, by which the pre-revolutionary debt was to be "republicanized" and consolidated with the new debt. While this act was a political necessity it was accompanied by a repudiation of past interest payments and the conversion of the floating debt into a funded debt. The *Grand Livre* evoked loud complaints from the *rentiers*. It was, moreover, the occasion of clashes between Cambon and Robespierre, who would have been less vehement had he not regarded Cambon as the center of the resistance he encountered in the committees. The defeat of Robespierre brought Cambon's political fortunes to their climax and enabled him to obtain what he had long desired, a decree of complete separation of church and state. But Cambon's record as a member of the Mountain, his sympathy with its survivors and his militarism prevented continued harmony with the Thermidorians. Except for a momentary return to the political stage in 1815, Cambon's career ended with the revolution of 12 Germinal.

MARCEL MARION

Consult: Arnaud, R., *Cambon* (Paris 1926); Marion, M., *Histoire financière de la France depuis 1715*, 5 vols. (Paris 1914-28) vols. II-III.

CAMBON, PIERRE PAUL (1843-1924), French diplomat. After serving successively as prefect of the departments of Aube, Doubs and Nord, Cambon was sent out in 1882 as resident general to Tunis. He played a prominent role in the organization of the protectorate, drawing on the British colonial system for guidance. In 1886 he was appointed ambassador to Madrid and five years later was transferred to Constanti-

nople, where at first hand he observed the German policy of peaceful penetration in Asia Minor and where he probably formed the opinions of German *Weltpolitik* characteristic of his later years. Following the Fashoda crisis (1898) Delcassé sent him as ambassador to London, where he remained until 1920. When Cambon assumed charge of the embassy the relations between the two countries were most strained; many Frenchmen had come to entertain the idea of revenge against England rather than against Germany. A hearty advocate of Delcassé's policy, which aimed at an Anglo-French understanding, Cambon may justly be described as one of the great architects of the Entente Cordiale. With dignified patience he studied British psychology and policy, and ably conducted the negotiations leading to the famous understanding of April 8, 1904. When the new entente was subjected to the severe ordeal of the first Moroccan crisis he carried on the discussions regarding eventual English aid for France and paved the way for the military and naval *pourparlers* of 1906 and the following years. From this time on he appears to have exercised a determining influence upon French foreign policy, which was particularly in need of direction because of the instability of the French ministries. He was instrumental in promoting the Anglo-Russian agreement of 1907 and helped steer the entente through the period of the Bosnian and the second Moroccan crisis. During the most anxious period of the first Balkan War he strengthened the entente by securing from Sir Edward Grey a letter (November 22, 1912) in which Grey agreed "that, if either Government had grave reason to expect an unprovoked attack by a third Power, or something that threatened the general peace, it should immediately discuss with the other whether both Governments should act together to prevent aggression and to preserve peace, and, if so, what measures they would be prepared to take in common." On the basis of this correspondence Cambon worked to bring about the immediate intervention of England in the great July crisis of 1914. With remarkable diplomacy he succeeded in leading Grey along the desired road. He remained in England throughout the World War, obviating difficulties and misunderstandings between the Allies. Cambon was the leading figure in that remarkable triumvirate of diplomats of pre-war France of which his brother Jules and Barrère were the other members. While Cambon's influence upon

French policy cannot always be determined, he assuredly deserves a preeminent place in the history of French diplomacy.

CAMDEN, WILLIAM (1551-1623), the most important English historian and antiquarian of the Elizabethan period. His *Britannia* was mainly responsible for the firm establishment about 1650 of the true outlines of English history prior to 1485. He produced the first scholarly edition of several of the early chronicles and diligently collected materials on English history, genealogy, topography and numismatics, which today form part of the important Cotton Mss. in the British Museum. He was an influential member, and perhaps the founder, of a society of antiquaries to which several later groups trace their origin. Through Cotton, Selden, Coke and others he provided much historical information used by the Commons in their struggle with the crown. He endowed a readership in history at Oxford, taking thereby a pioneer step in the development of history as an independent discipline. As early as 1581 his scholarship attracted continental attention, and he furnished information about England to the French jurist Brisson, the geographer Ortelius and the French historians De Thou and Dupuy. Camden was also a notable educator. He was for many years master at Westminster School, wrote a Greek grammar for secondary schools (1597), used until the nineteenth century, and played an important part in the revival of the study of Anglo-Saxon.

ROLAND G. USHER

Important works: *Britannia* (London 1586, new ed. by author 1607), tr. by P. Holland (London 1610; 4th ed. 2 vols., 1772), and by R. Gough (from the 1607 edition, 3 vols., London 1789), the second edition of the latter (4 vols., London 1806) including an extended biography of Camden; *Epistolae*, ed. by Thomas Smith with a life of Camden (London 1691).

CAMERALISM. The term *cameralism* is applied to the associated political ideas gathered about the centralizing practices and tendencies in administration, finance and economic policy which characterized the absolute monarchy in Germany and Austria around the middle of the

eighteenth century. The term also designates the system of political sciences of the same period which placed itself at the service of the absolute monarchy and attempted to work out a systematic account of the functioning of the various administrative services as a basis for the training of public officials.

Cameralism is properly the German and Austrian variety of mercantilism. What differentiates the mercantilism of these two countries from the mercantilist systems of other parts of Europe is the circumstance that only in Germany and Austria did internal political consolidation coincide with the introduction of mercantilistic policy. The process of unification of political elements which had been financially, legally and economically separate started in Prussia under Frederick William I and its effects were still evident in Austria in the attempted reforms of 1748 under Maria Theresa. This process was characterized by centralization of administration, liberation of industry from guild organization, the creation of uniform municipal law and the formulation of a mercantilistic economic policy. In Austria in particular absolutism was inaugurated by the centralizing of administrative law. The most important stage in the development of the process was the centralization of financial legislation. The essential features of this reform were the issuance of tax ordinances valid throughout Austria, the designation of agencies of the central government for the collection of these taxes and the reorganization of the royal exchequer as a national treasury for the whole empire.

Cameralism falls into two distinct phases of development if we exclude, as we properly should, the juristic tax literature of Bornitz, Besold and Klock, which limits the function of the state and consequently stresses the question of the justice and the legality of imposing taxes. The all embracing state interventionism of the mercantilistic system and more specifically of cameralism excludes the question of justice, maintaining the position that no limits upon the public revenue can be fixed. To the first phase of cameralism belong the three great political economists of the time of Leopold I, Becher, Schröder and Hornick, in whose writings the different aspects of cameralism appear with varied emphasis. Becher concentrates on the internal political and economic relations of the three states, Schröder advocates absolutism in the form of the monarchical state, while with Hornick the idea of the collective Austrian state

occupies the foreground. In its second phase cameralism was developed and systematized as a political science through the rise of administrative science, a development characterized by the establishment, under Frederick William I, of the first university chairs in cameralism (Dithmar in Frankfurt a. Oder and Gasser in Halle a. Saale). Among the forces which forged the concept of administration and transformed early cameralism into administrative science was the problem of handling the vastly increased range of activities of the rising paternalistic state. Other forces operating in the same direction were the increasing powers of the central administrative departments and the constant extension of state interference in the life of society, which brought into the foreground the question of the justice of that interference. The stratum of autonomous associations, such as the guilds, which had stood between the subject and his ruler, had been abolished. Ruler and people now confronted each other directly and a new definition of their reciprocal relations had to be worked out. More and more attention was given to the problem of justifying the steady expansion of state intervention. To this end the doctrine of natural rights was drawn upon.

What characterized the German natural rights doctrine was not the concept of individual freedom but that of the union of wills, the origin of the general will of the state in the joining together of individual wills in the social compact. The natural rights concepts of transferability and alienability of powers afforded a basis for the juristic and political relations of ruler and people. These relations were conceived of as those of mandatory and mandator. Every exercise of power on the part of the ruler could be linked up with his legal position as mandatory. This doctrine of natural rights as developed by Pufendorf formed the theoretical basis of enlightened absolutism, the classical justification for the doctrine of the paternal state. The doctrine was further developed by Thomasius and Wolff. To stake out the limits of state power so as to provide legal sanction for state intervention was the task that fell to the natural rights jurisprudence; the duty of cameral science was to supply the positive content for these occasions of intervention and to systematize the ever increasing number of state tasks.

The most distinguished representatives of later cameralism are J. H. G. von Justi and Joseph von Sonnenfels. The cameralistic doctrines of both are founded on natural rights theories of

the state. For them the object of the state is one of eudaemonistic utilitarianism, the general happiness of the subjects. In their economic theory the cameralists lay chief emphasis upon increase in population. The food supply and the population vary in direct relation with each other. Increase in the national wealth is to be attained by enlisting additional labor; hence aliens are to be attracted to the state by tax exemption and subsidies. In contrast to the mercantilism of the west, German cameralism stresses not so much commercial expansion as industrial centralization. The balance of trade theory is applied to the doctrine of population as a balance of employment. By freedom of trade is meant the abolition of state price control, monopolies, trade associations and privileges.

Cameralistic tendencies and technique predominated in Germany until far into the nineteenth century. Cameralism relaxed its hold only under the influence of Adam Smith's doctrines, which were spread through Germany by Jakob Soden and Hufeland. Important in this connection also is the transformation which the German natural rights theory of the state suffered under Kant. Yet even Rau, whose strenuous advocacy of free trade bears the stamp of Adam Smith, shows evident cameralistic influence in his organization of the subject matter. Traces of that influence are also visible in the all inclusive administrative doctrines of Lorenz von Stein.

Cameralism as the science of administration especially helped to develop those branches of learning that are useful in state administration. Thus statistics, valuable for census purposes and for a grasp of foreign trade, began as a branch of the cameral sciences. The sharp distinction between fiscal science and public finance goes back to cameralistic influences.

The common factor underlying all cameralistic systems, the earlier as well as the later, is their close relation to the state. Criticisms of cameralism in economic literature center in this relation. While W. Roscher adhered to an economic interpretation of cameralism, Lorenz von Stein made clear its significance for political science in general and Marchet worked out the administrative ideas in the cameralistic system. Albion W. Small conceived of the cameralists in broader terms, as political scientists. Axel Nielsen stressed the cameralistic theory of the state. Zielenziger tried to distinguish clearly between the ideas of mercantilism and cameralism. Louise Sommer devoted herself to the question whether cameralism, or mercantilism,

can be regarded as a scientific system. There is no such procedure in cameralism as a conscious resort to any fundamental theoretical code of principles which is conceived of as the basis of the whole movement, as is the case with the physiocracy in its dependence on Quesnay's *Tableau économique*. The unifying principle in cameralism does not lie in conscious intellectual relations which would permit one author to build upon another while developing his own particular contribution. And yet the question of whether cameralism has any theoretical content, hence whether it deserves to be called a system, must be answered with a decided affirmative. The dogmatic content is not to be sought primarily in the developed theory. Cameralism is simply a historical system, which assumes unitary form only in retrospect by virtue of its consistent interpretation of the trends of thought and the values of its age. The principle which operates to make of it a system lies not in a conscious theoretical foundation but in a harmonious group of unconscious reactions having an essentially political orientation. This orientation is at the same time of decisive importance in determining the formulation of the particular economic doctrines. The condition making for system building is the fact that the problem of the rising state is the focus of cameralistic interest. In their more or less primitive speculation on social phenomena the cameralists consistently looked upon the state as the ultimate social reality. The period was one in which scientific division of labor and specialization had been barely attempted, in which political economy in its early, cameralistic beginnings was treated in connection with theories of the state, ethics, philosophy and natural science. In these circumstances a sharp differentiation of spheres and methods of thought could hardly be expected. Cameralism is interpenetrated by elements of other sciences, especially of those disciplines which had the greatest significance in that day, the theory of the state and the natural sciences, which were then beginning to flourish.

CAMERON, ANDREW CARR (1834-90), American labor leader. Cameron's career epitomizes the rising national labor movement in the United States from the Civil War until the late seventies. His militant independent editorship of the *Workingmen's Advocate* (Chicago 1864-77), the official organ first of the Chicago Trades Assembly and later of the National Labor Union, made it not only the leading labor journal of the period but one of the few bright records in the history of the American labor press. This weekly periodical, with its nation wide circulation, not only reflected the temper of American labor—its advocacy of independent political action, of producers' co-operation, of the eight-hour day, of an alliance of industrial with agricultural labor and, during the post-war depression, of "greenbackism"—but did much to clarify and popularize these issues.

Cameron was prominent also in the Chicago typographical union; in the Chicago Trades Assembly, of which he was president for four years; as president of the Grand Eight Hour League; as an organizer of the National Labor Union; and as American delegate to the Fourth Congress of the International Workingmen's Association at Basel in 1869, where he claimed to represent 800,000 organized workers.

The outstanding emphasis of his *Address of the National Labor Congress to the Workingmen of the United States* (Chicago 1867), a comprehensive survey of his own social program, was on independent political action. When in the late seventies labor party agitation began to yield again to an interest in direct economic and industrial action Cameron's influence gradually declined.

CARA COOK

CAMORRA was a secret society which originated and operated in the province of Naples; in its last stage it was described as the "greatest criminal organization in the world." From 1820 until its extinction in 1922 the Camorra, while identified with the lowest stratum of Neapolitan life, had periodic contacts with the upper classes not only in Naples but also in other parts of the peninsula. It cannot be dissociated from the regime of the Spanish Bourbons, who suppressed every popular political expression, or from the succeeding reign of the house of Savoy. Its changes in organization and character more or less reflected such events as the abortive Carbonari revolution of 1820, the revolt of Young Italy in 1843, the local repercussions produced by the Sicilian revolution of Ruggiero Settimo and the drastic prosecutions of members of the Società Unità Italiana in 1848, the advent of Garibaldi followed by the evacuation of the Bourbons in 1860, the absorption of Naples by the kingdom of Italy in the following year and finally the World War and the rise and dominance of Fascism. More intimate influences in shaping its destinies were the illiteracy and idleness general in Naples, a land in which bare subsistence may be obtained with no great effort.

The Camorra was first heard of as a movement for organized protection among released political offenders who in 1830 established themselves in the city of Naples. The more criminal elements associated with the organization formed gangs which preyed upon the unprotected in the ill governed city or, for a consideration, offered immunity. This society's smuggling activities brought it into contact with the predatory authorities, both civil and ecclesiastic. High personages paid for crimes committed for their benefit or for immunity and the police often employed the society to expose non-Camorrist crimes. The Camorra "taxed" officials holding lucrative positions and secured large revenues from brothels, gaming establishments and illegal lottery bureaus. It probably reached the acme of efficient organization between 1830 and 1848. There was evolved a curious ritual of initiation with tests of courage and loyalty, oaths sworn on pistol, dagger and poison and penalties for infringement, ranging from maiming to death; there were signs for secret communication and a special vocabulary. The members served novitiates before they were assigned or permitted to undertake major crimes. There was a "lower" or *bassa* Camorra and a "higher" or *alta*. The latter

was the governing body and maintained secret affiliations with the authorities and influential persons.

The withdrawal of the constitution of 1848 brought the society into politics. In 1851 the administration of Ferdinand II employed *basisti* spies for the apprehending of political prisoners; Gladstone estimated the number of political prisoners at the time as between fifteen and twenty thousand. Under Francis II the court camarilla attempted to suppress the Camorra. In reprisal the society transferred its allegiance to the Garibaldi Committee and was an important factor in driving out the Bourbons in 1860. Its services were accepted for a time by the new provincial government under the crown of Italy as an auxiliary of the police, but it soon got out of hand and in 1862, 1877 and 1899 determined efforts were made to suppress it. The report made in 1901 by a royal commission of inquiry brought into being an "Honest Government League" in Naples which succeeded in having all Camorrist candidates defeated at the provincial and municipal elections and considerably lessened the Camorrist influence in the *malavita*, or underworld. Though serious and disinterested publicists wrote that the Camorra was no more, evidence of its presence periodically came to light and the number of unpunished crimes continued to increase.

In the summer of 1906 the murder of a couple named Cuocolo took place. Both husband and wife had the reputation of being *basisti* of the Camorra; both were suspected of working with the Questura, or municipal police. For a variety of reasons the government at Rome was anxious to bring about reform in Naples and hence undertook a secret investigation which lasted five years. After a trial of sixteen months (March 11, 1911, to July 8, 1912) at Viterbo thirty of the accused were convicted. The constant rulings of the presiding judge to confine the procedure to the Cuocolo murders per se and to circumstantial evidence, the persistent manner in which evidence indicting the society itself was disallowed, constant warnings given the prosecution by the bench and subsequent action against witnesses showed that the Camorra still had its protectors in high places. In spite of the fact that the leaders of the society were in prison the Camorra was in a fair way to restoration before the World War. After the war the activities of the Fascist organization absorbed its energy and operated to check its recovery.

In social, political and criminal history the

Camorra is unique. It is doubtful that it ever, as an organization, exerted any measurable influence outside of Italy, although the murder of a New York lieutenant of police at Palermo in 1909 by members of the Sicilian Mafia was very probably instigated by Alfano, head of the organization, in revenge for his deportation from New York.

CAMPAIGN, POLITICAL. Within the general framework of similarity shared by all democratic institutions, the organization and conduct of political campaigns vary from country to country. The system of government of itself produces certain variations. Thus the cabinet system, with its ever present threat of surprise elections, requires a more continuously functioning campaign machinery than does the congressional system. Within each of these two major types, furthermore, variations will occur which are traceable to the political psychology and tradition of the people. Thus campaigns in England differ from those in France, campaigns in the United States from those in Latin American countries. American phenomena may, however, fairly be regarded as typical. Since it was in the United States that the experiment with democracy began, some decades in advance of European countries, it is here that we should expect to observe party processes which, by reason of greater maturity, have something like universal significance. The presidential campaign, occurring at four-year intervals and bringing into play all the elements of party organization and strategy, affords the best means of approach to American practise.

A political campaign, like a military campaign, requires organization. There must be a general staff responsible for preparing plans and co-ordinating effort, a chief of staff who directs operations and a hierarchy of commissioned and

non-commissioned officers who transmit orders to the rank and file. Democracy involves the cooperation of millions in a common enterprise; and the parties, seeking to mobilize and regiment the vast electorate, must set up machinery appropriate to their task. This machinery assumes in the United States the form of a pyramid, with the national committee at the apex and the mass of party members, segregated in precincts or election districts, at the base. Until late in the nineteenth century it existed solely by virtue of party action and lay outside the domain of law. Today the national agencies still retain that voluntary character; Congress has not attempted, and probably has no power, to regulate them. But within the several states the situation is very different. Primary laws define party, lay down the conditions of party membership, describe the composition of state and local committees, the way in which they shall be chosen and, in general language, the functions which they shall perform. Such regulation by statute—even though rudimentary in some states, particularly in those of the solid South—stands out as a characteristic feature of American politics.

Party organization in the United States begins with the precinct or election district, the smallest political division of the state. Here, as a rule, the party members choose at the primary an executive officer who serves as a link between the upper ranges of the organization and the individual voter. Above this officer are numerous committees, corresponding to the more important electoral areas—assembly districts, counties, senatorial districts—and, since the control of these depends upon what happens in the various precincts, he must swing the primary vote. His own political life is at stake. He wins success by tireless effort, by getting to know all the party adherents, their business interests, their tastes and inclinations, their vulnerable spots. The really important committees are those of the county and the state; in larger cities, because of the density of population, the ward is interposed between precinct and county as a base of major operations. In three fourths of the states the county committee consists of the precinct leaders. The county chairman, who has access to an extensive patronage in the form of public offices and contracts, may become a dominant figure, holding his place over a long period and wielding the authority of a benevolent despot; or he may be merely the henchman of a county boss who works behind the scenes. The state central

committee sometimes stands in a truly hierarchical relation to the committees below, its members consisting, for example, of the congressional district chairmen. More often the members are chosen at the primary or state convention and thus have an independent origin. Even so, the necessity for some concentration of power in the management of party affairs and the conduct of campaigns gives the committee great prestige as long as the party is united and harmonious. Its chairman, however, is seldom more than the titular head of the party organization. Effective leadership commonly rests with the governor, a United States senator or a crack politician who holds no office; and his authority permeates the complex mechanism from state committee down to precinct executive.

The national committee consists of a man and a woman from each of the states, territories and insular possessions. It is elected by the national convention late in June of the presidential year; and, since the convention does in fact merely ratify the choice of the various state delegations, which in their turn are instructed by the state committees, national party organization is in a measure derived from state party organization. Close and cordial cooperation between the two is insured in other ways. In the presidential year public interest centers upon the struggle for possession of the chief magistracy. Every other campaign takes its tone from the presidential campaign; every other candidate finds his fortunes involved in those of the presidential candidate. Moreover the national committee wields a sort of financial hegemony, exhausting sources of supply in the collection of its campaign fund and thus making the state committees somewhat dependent upon its largess. These circumstances have a still greater effect in subordinating the congressional and the senatorial campaign committees, which are concerned respectively with the election of representatives and senators. Tradition has established the right of the presidential candidate to name the chairman of the national committee. This arrangement gives the victorious faction, when there has been a bitter contest for the presidential nomination, some security against sabotage; it insures an intimate, confidential relationship between the candidate and the man who manages his campaign. The candidate may reserve to himself the final word in matters of high strategy, as did Roosevelt in 1904 and Coolidge twenty years later; usually, however, he stands aside. The

chairman, absorbing the powers of the committee, exercises an almost autocratic authority. He does, of course, confer with the candidate and his executive committee; he requests and takes advice from many quarters. But rapidly shifting situations in a campaign do not permit the delay that is involved in seeking a collective decision.

The national party convention selects the candidates and adopts a platform, a long document which surveys the whole field of national politics and makes pronouncements upon a great variety of questions. Now and then it sounds a clear note upon some paramount issue. Usually it bears the marks of artifice, ambiguity and dexterous evasion. Its anaemic character reflects the very essence of the democratic principle. The party is a vast combination of voters brought together upon a common ground by mutual concessions and by the harmonizing of group and sectional interests. Each separate element must be ready to make sacrifices, abandon extreme claims and adjust itself to the average sentiment. What satisfies no particular group may give tolerable satisfaction to the party as a whole. Toward the middle of August the presidential candidate delivers his speech of acceptance. He gives precision to the vague language of the platform. Having observed the trend of opinion, he emphasizes one declaration, tones down another and perhaps commits himself and the party upon some issue which the convention has overlooked or ignored. The people give ear. They are now listening to an authentic voice. Indeed, they are coming to regard the candidate rather than the convention as the responsible expositor of policy and principle.

The national chairman, capitalizing popular interest in the opinions and personality of the candidate, always gives him as much prominence as possible in the campaign. The methods vary. Coolidge in 1924 made no political speeches; like McKinley in 1900 he felt that a president seeking reelection should hold himself aloof from partisan controversy. Nevertheless, his personality, as presented to the electorate by the most ingenious propaganda, became the chief Republican asset. Harding, like McKinley in 1896 and Wilson in 1916, spoke frequently from the front porch of his Marion home. The front porch campaign has many advantages; the candidate preserves his dignity and his physical well-being; his speeches are prepared with deliberation and so escape incoherence and mere repeti-

tion; the newspapers, receiving advance copies, print them in full. On the other hand, the swing around the circle, with hundreds of speeches from the rear platform of a train, gives millions of people the chance to see the candidate in flesh and blood, hear the actual tones of his voice and become acquainted with his personality. This method of campaigning began with Bryan in 1896. It continued with Roosevelt, Taft, Hughes and Cox. At present, however, it is condemned by political experts for, as the candidate succumbs to the perpetual strain, his speeches steadily degenerate in quality, and press representatives find little copy in the improvisations of a tired mind, incapable of generating fresh ideas. In the campaign of 1928 a new factor was introduced. Both parties used the radio as a means of circulating through the whole nation the proceedings of the conventions, the speeches of acceptance and the speeches of the candidates during the campaign. The Democrats spent nearly \$600,000 for this purpose, the Republicans nearly \$500,000.

Speech making is not, of course, confined to the candidates. The national committee sends out ten or fifteen thousand speakers, the local committees a much greater number. There is a terrific deluge of campaign oratory. It descends upon a small street corner gathering from the toungeau of an automobile and upon the great throng that packs a city auditorium. It inundates the whole community from the columns of the press and from the loud speaker of the radio. Mass meetings, preceded, it may be, by parades or other colorful demonstrations, appeal to the emotions still more than to the intellect. They generate or confirm enthusiasm among the rank and file of party adherents. Missionary work for the conversion of important groups—sectional, economic, racial, religious—goes forward at the same time. According to the particular state, success may depend upon the attitude of the dairy farmers, or the Negroes, or the Mormons. Indeed, the electorate is composed of interest groups rather than of individuals; and in approaching these groups infinite care must be taken to select the right kind of gospel and the right kind of missionary. In one case the speaker must show that the tariff on raw wool does not affect the profits of the woolen cloth manufacturer; in another he must dexterously fan the flame of prejudice and bigotry. There is danger in the appeal to base emotions, however, and in the attempt to besmirch a candidate by innuendoes and whispered aspersions upon his

private life. The spirit of fair play runs strong.

As an instrument of publicity the printed word is, perhaps, more influential than the spoken word. At any rate, the newspapers play a most important role. Many newspapers attach themselves to one of the major parties and give willing support throughout the campaign. Others, normally independent, take sides because the candidate or his policies attract them. The press bureau at party headquarters, whose business it is to supply ammunition, varies the character of its services with the type and importance of the newspaper. Skilful writers turn out news items, articles, editorials. Latterly a great deal of attention has been given to advertising; a paid advertisement carries propaganda into neutral or hostile territory, which the free publicity of party organs will not do. The billboards were used effectively for the first time in 1916, when the Democrats displayed the slogan, "He has kept us out of war," along with the picture of a nappy home in peace. Four years later the Republicans gave currency to the slogan, "Let us be done with wiggling and wabbling." While the press is the most effective medium of propaganda, party managers set great store by pamphlet literature, centering upon the outstanding issues and the career of the presidential candidate. These numerous pamphlets, varying in size from four pages to eighty or even more, are printed and distributed in enormous quantities and at great expense. The most interesting publication of the national committee is the campaign textbook, a volume of four or five hundred pages for the aid of party workers and journalists.

The effort of the campaign is not spread evenly over the country. In certain areas, where one party or the other has an assured predominance, no serious contest occurs. It is the doubtful states that become the theater of active operations. From them the candidates are chosen; for them the issues are defined; in them the fighting forces are concentrated. The national chairman, trying to estimate the drift of popular sentiment in these doubtful areas, must have accurate information. Reports will be laid before him from every precinct captain in a given state, showing whether more energetic measures are required. There may be a second elaborate canvass of the voters, perhaps even a third, in order to see how well the new drive is succeeding.

The various instruments of publicity—advertising, radio broadcasting, printing and

distributing literature—entail heavy expenditure. We have no means of reaching an accurate computation of the aggregate cost to the major parties. The available figures show only what the national and state committees have spent, which in 1928 amounted to \$16,500,000 for Republicans and Democrats together. The expenditures of local committees and individual candidates must likewise reach a gigantic sum. Aside from the assessments laid upon office holders and candidates for office, the party funds are derived from voluntary contributions. Toward the end of the last century big business began to furnish enormous subsidies, often with the purpose and expectation of influencing public policy. This interested generosity has been curtailed by legislation. In order to allay popular suspicion the national committee has at times put a limit upon the size of individual subscriptions and relied upon collecting small sums from the great mass of party adherents. The outcome has not been encouraging. Latterly the source rather than the size of a check has been the important consideration; money is welcome in any amount so long as it is not tainted and comes without any implied obligation attached to it. In 1928 one Republican contributed \$172,000; three Democrats more than \$100,000 each. On the other hand the number of individual contributions went beyond any previous record: 145,000 in the case of the Republicans and 90,000 in the case of the Democrats.

How should the campaign be appraised from the standpoint of social values? In the first place it is a necessary incident of democratic politics, an inevitable corollary of the democratic system of election; and convinced democrats regard it, with something more than complacency, as a means of popular education. The people put aside other interests, give all their attention to the prolonged debate on public affairs and prepare to announce their solemn verdict. The campaign emphasizes civic virtue and civic responsibility. According to the skeptics, however, it appears as a colossal travesty, as a calculated effort to bamboozle the great mass of standardized mediocrity. The poison gas of propaganda overpowers judgment and blunts sensibility. At the end the bewildered voter staggers blindly into the polling booth, incapable of making any rational decision. Both these views are mistaken; for both exaggerate the effectiveness of the campaign. There is, at least, reason to believe that the results are quite disproportionate to the cost in money and energy.

The voter's interest in politics is not altogether spasmodic; he does not suspend judgment and wait for the campaign to enlighten him. His attitude toward the parties, if not grounded securely on interest or prejudice, takes shape gradually under the impact of political events. The *Literary Digest* poll, accurately forecasting the outcome of the elections in 1924 and 1928, helped to burst the iridescent bubble of campaign oratory and literature. It does seem that the party appeal can be effective only if it is continuous—culminating, not beginning, in the period just before the election.

CAMPANELLA, TOMASO (1568-1639), Italian philosopher. He was one of those who represented in greatest degree the tragic struggle of the Italian Renaissance between the mediaeval and the modern, a struggle of opposing forces both in the outer world and within the mind. Testimony of this conflict is afforded by the wretched thirty-years imprisonment inflicted upon Campanella on the charges of heresy and of conspiracy; it is further revealed in the contrast between his naturalistic-gnosiological ideas, wherein he followed Telesio and Galileo and anticipated Descartes and Leibnitz, and his belief in magic and astrology; between his affirmation of natural religion and his adherence

to the Counter-Reformation; between his defense of natural right and the mediaeval conception of his theocratic utopia.

According to Campanella's social philosophy all beings are united by the bond of natural religion. The latter is immanent in every creature as the instinct for self-preservation, which is at the same time the instinct to unite with the supreme principle. The form which natural religion assumes in man is the compulsion of natural right, of universal brotherhood, of striving toward godhead. Proper understanding of the nature of man must become the basis of politics if the latter is to be transformed from art into science. In the human instinct for self-preservation, which Machiavelli regarded as the source of nothing but egoism, evil and war, Campanella saw the force engendering the need for union and law and the impulse to conform to eternal natural law. This harmony of politics and ethics is the theme of Campanella's two utopias: the universal theocratic monarchy described in *Monarchia di Spagna* (Amsterdam 1640) and other works and the communist *Città del sole* (first published as *Civitas solis, idea reipublicae platonicae in Realis philosophiae epilogisticae*, Frankfurt 1623). Both of these works appear in the complete edition of Campanella's writings by d'Ancona (Turin 1854).

Like the utopias of More and other Renaissance writers the *Città del sole* owes much to Plato's *Republic*; it owes still more to contemporary accounts of the Incas and to the example of religious communities such as those founded by the Anabaptists and by Catholic missionaries. To community of goods Campanella added that of women. He subjected all social life—economic, sexual and educational—to stringent regulation. It is significant that he animated his whole community with the conceptions of natural right and equality.

CAMPBELL, ALEXANDER, nineteenth century British trade unionist. He was early a follower of Robert Owen and in the thirties edited Owenite journals in Glasgow. He attempted to form a general union along Owenite lines and was also secretary of the Glasgow joiners' union in the thirties as well as founder

of a new union of joiners in 1856. Two years later he became the virtual founder of the Glasgow Trades Council. He had a continuous connection with the labor press, becoming in 1860 editor of the Glasgow *Sentinel*, the organ of the newly formed National Association of Miners. He clung to the Owenite tradition and as late as 1868 presented to the Royal Commission on Trade Unions a detailed argument for Owenite societies of producers.

Campbell's most significant achievement was the inauguration and leadership of an agitation among trade unions for an amendment of the Master and Servant Law which contained, among other harsh and oppressive features, a provision that a breach of contract of service committed by a workman was a criminal offense punishable by imprisonment, but if committed by an employer entailed only a civil suit for damages. The trade union conference of May, 1864, held in London as a result of this agitation, was the first spontaneous meeting of trade union delegates to consider measures for their general welfare, and the amendment to the law enacted in 1867 was the first positive trade union success in legislation. Campbell and his associates thus helped to give a new direction to trade union policy and facilitated further advance by encouraging political action.

Consult: Great Britain, Parliament, House of Commons, "Report of the Select Committee on Master and Servant" in *Parliamentary Papers*, vol. xiii (1866) 14-23; Webb, Sidney and Beatrice, *The History of Trade Unionism* (rev. ed. London 1920); Postgate, R. W., *The Builders' History* (London 1923).

CAMPBELL, JOHN, BARON (1779-1861), English judge. He became eventually Lord Chancellor of England. As judge he was sound but not brilliant, and perhaps his greatest contribution was to establish the doctrine that the House of Lords is absolutely bound by its own judgments. His reputation is based rather upon his genuine passion for legal reform and on his literary labors. His report as head of the Real Property Commission of 1828 has proved of considerable value in subsequent legislation. Campbell supported a whole series of statutory reforms, and three acts which are still of great importance bear his name: the Libel Act (1843), establishing truth as a defense in a criminal prosecution for libel if the publication was for the public benefit; the Fatal Accidents Act (1846), permitting suit by the near relatives of

the deceased in case of wrongful death, thus derogating from the ancient maxim of the common law, *actio personalis moritur cum persona*; and the Obscene Publications Act (1857), the basis of the present literary censorship in England. Among his works the most famous are *The Lives of the Lord Chancellors* (7 vols., London 1845-47; 7th ed. in 12 vols., Jersey City 1881-85) and *The Lives of the Chief Justices* (3 vols., London 1849-57; new ed. in 5 vols., Northport, N. Y. 1894-99), of which the former gained especially wide attention. Despite its original materials it has been attacked for gross inaccuracy and bad taste and for "adding a new terror to death." Campbell also published his own *Speeches* (London 1842) including his long argument for the House of Commons in *Stockdale v. Hansard*, the leading case on parliamentary privilege.

(London 1906-08) vol. II, p. 127-218; Sugden, E. B., *Misrepresentations in Campbell's Lives of Lyndhurst and Brougham* (London 1869); Ernst, M. L., and Seagle, William, *To the Pure* (New York 1928) ch. vi.

CAMPILLO Y COSSIO, JOSÉ (c. 1695-1743), Spanish economist and statesman. In 1741 he became prime minister and during his brief term succeeded in substituting a system of direct tax collection for tax farming. He was responsible for various other reforms and through his writings considerably influenced later colonial policy.

His most famous work is *Nuevo sistema de gobierno económico para la América* (Madrid 1789), written in 1743, in which he urged the necessity of harmonizing government with economic policy. He criticized the government of Spanish America, blaming it for the wretched agricultural conditions and the misery of the Indians. He deplored the fact that native manufactures were growing to the detriment of the mother country and that the maximum importation from Spain represented only one twentieth of American consumption. As remedial measures he proposed: to give the Indians lands, tax free for fifteen or twenty years, after which time they would pay a moderate rent; to use Indians as artisans; to organize mortgage loan companies and *pósitos* (public agricultural credit institutions); to allow only such factories as did not compete with Spain or as found cheap and

abundant raw material in America; to diminish contraband trade by reducing the customs duties on foreign commerce; to exempt Spanish commerce from taxation and to permit free trade within Spanish America to Spaniards in Spanish boats; to encourage commerce between New Spain and Asia via Acapulco and the Philippines; to have large companies establish commercial distribution centers in strategic places; to organize a fast mail service; and to establish the office of economic governor.

FERNANDO DE LOS RÍOS

Consult: Rodríguez Villa, A., *Patiño y Campillo* (Madrid 1882).

CAMPING, the practise of living in a temporary lodge or shelter, has appeared intermittently throughout history but has become a major social phenomenon only within very recent years. Camping is essentially a folkway of an urban civilization; primitive or pioneer groups may camp temporarily when necessity dictates, but it is only a city people that adopts the temporary but periodic retreat to the out of doors as a form of recreation and a phase of the accepted ways of living. Moreover, while every period of extensive urbanization has been accompanied by movements back to the land, in no other time but our own has a return both easy and temporary been possible for the majority of people.

It is in the United States that camping has been most markedly woven into the pattern of social life. The Sunday picnic in the country had become habitual to many a townsman of pre-war Europe; in the post-war youth movements, especially in the *Wandervögel* of Germany, the impulse to a free and "natural" life found expression in camping and living out of doors; but only in the United States has camping developed into a national habit and an organized industry. A variety of factors have contributed to this development: the persistence of the traditions and impulses of the pioneer period, the presence of large areas of unused land, the looseness of family ties and the need for new groupings with vital group interests. In more recent years the automobile and the publicly constructed motor road have given a new impetus and a new form to camping; while the spread of the recreation movement, with its emphasis on the values of out of door life, have lent it a new rationale.

The impetus to the founding of the earliest organized camps in this country was afforded

by the boys' and girls' club movement of the late nineteenth century, and for a number of years organized camping has been essentially an educational and recreational project for children. Thus the first organized camp of which there is any record was founded in 1872 at Lake Waramaug, Connecticut, by Frederick William Gunn, headmaster of the Gunnery School. Although it enrolled almost the entire membership of the school it was primarily a recreational agency. Religious groups were also active in the establishment of camps; one of the earliest was a small camp established in 1880 by the Reverend George W. Hinckley for boys from his church. Five years later Camp Dudley, which is still in existence, was founded at Westport, Lake Champlain, New York, under the auspices of the New York State Young Men's Christian Association. In 1881 what is commonly regarded as the first private camp in America was opened at Chocorua, New Hampshire, by Ernest Balch.

During the next few decades camps of this type, established by schools, churches, social welfare organizations and private individuals, grew in number and popularity. Within a short time certain techniques and customs of camp organization had developed and might be found in but slightly different form in all camps. The organized camp, under whatever auspices it is conducted, is characterized by the fact that the camp as a corporate entity assumes responsibility for the welfare of the camper. It ordinarily provides a director of organization and activities and a well integrated daily program. The campers are often divided into groups, each under the direction of its counselor, who is a paid staff member responsible to the director. Athletics, woodcraft, nature lore and amateur dramatics play an important part in the program. With the growth among wealthy and middle class families of the practise of sending their children to camp for the whole of the summer, studying and tutoring programs of great variety have been adopted by many boys' and girls' camps.

As the camping movement became better established, a variety of new forms developed. For the older boy or girl the organized pack-trip camp in the west and southwest of the United States or the canoe camp in the Adirondacks, Maine and some of the Canadian parks have become popular. To meet the needs of the employed and less wealthy groups week end camps have been established both commercially and by such organizations as the Young Men's and

Young Women's Christian and Hebrew associations, social settlements, labor unions and churches. Most commercial camps for adults stress special week end features. The family camp has been of increasing importance.

The possibility of combining the ordinary features of camp life—the outdoor activities, the recreational methods, the escape from accustomed routine—with special ends and programs has been recognized by many groups. A great variety of special camps are now in existence. Citizens' Military Training Camps conducted by the United States War Department at fifty-three centers accommodated, in 1929, 37,979 young men between seventeen and thirty-one years of age. The government also conducts Reserve Officers' Training Camps, while several of the states have short term camps, usually of two weeks' duration, for the training of militia. Engineering schools have established technical practice camps chiefly for field work in surveying; and tutoring camps for coaching in preparatory and college subjects are growing in number. Camps devoted primarily to professional training in music, drama, art and rhythm have appeared in recent years. National religious bodies have made frequent use of short term camps conducted in connection with summer conferences. College liberal clubs and organizations like the League for Industrial Democracy also utilize such camps, which are becoming increasingly important as the adult education movement in this country copies the pattern of the European week end and summer conferences. The primary purposes of some camps, conducted, for instance, by certain religious bodies and by the Communist party, is undoubtedly propaganda. The United States Department of Agriculture uses its Four H Club camps to stimulate in older boys and girls an interest in the activities of farm life. Of increasing importance are camps for undernourished, disabled, convalescent and problem individuals. More than three hundred disability camps devote their entire efforts to children and some of the most important among them provide psychiatric care. Camps afford unique opportunities to control the life situation of non-institutionalized individuals as clinics do not; and universities and child guidance clinics are increasingly recognizing the value of camps as social laboratories for the study and treatment of behavior disorders.

Less easy to classify and enumerate, but of growing importance, are the many types of unorganized camps which may be found through-

out the country. Such camps may be conducted by individuals or by small groups. They may be temporary or permanent, entirely independent of supervision and control or subject only to police, fire and sanitary regulations. The automobile has brought into existence a totally new kind of camp, the tourist camp, most temporary of modern homes. Tourist camps are conducted by the federal government in the national parks, by state, county and municipal bodies, by semi-public bodies such as chambers of commerce, and as business ventures. They vary in character from the simplest of structures to elaborate groupings of buildings and recreational facilities.

Statistics cannot express the importance of the growth of camping habits. Yet the incomplete figures which are available do at least give some indication of the extent of the phenomenon. Official returns to national organizations indicate that, in 1929, 7368 organized camps accommodated 1,142,500 campers, chiefly children, for periods varying from one week to nine weeks. Approximately 300 municipal and state camps accommodated 80,000 people, of whom 80 percent were children. National and state parks reported a total of 1,533,000 campers, about one third of whom were children. Private camps for children reported an enrolment of 100,000, but it is conservatively estimated that the number of private camps not reporting enrolment exceeds the number registered. No figures are available as to the number in adult commercial camps, which have experienced a continuous and recently somewhat accelerated growth.

The widespread popularity of camping is both symptomatic of a society characterized by a high degree of social mobility and in itself a factor contributing to the increase of mobility. The tourist camp has arisen most directly in response to the needs of a touring population; it contributes to making trips throughout the country possible for ever increasing numbers. In it the greatest mixing of social groups occurs. But because of the temporary character of most of the contacts it furnishes it may have less effect on social attitudes than the more permanent type of camp. In these also groups with very different backgrounds associate in common activities. Moreover, not only the vast majority of camps for children but also most of those for adults utilize organized programs which stress certain values and aim to develop socially acceptable attitudes and conduct. Indeed, leadership of camp activities is becoming an accepted

profession. Training courses for such leaders are conducted annually by as many as twenty recognized colleges and universities, by local community groups and by such national agencies as the Young Men's and Young Women's Christian associations, Boy and Girl Scouts, Camp Fire Girls, Woodcraft League, Camp Directors' Association, American Red Cross and the United States Department of Agriculture.

In such indirect ways common traditions of camp organization and camp life are built up. A more direct impetus to standardization of camping techniques comes through the establishment and operation of camps by municipal and other governmental bodies. State boards of health generally have enacted codes of sanitation applicable to camps, and they are rapidly extending the range of their supervision and control over all camps. Within recent years there has been a definite trend toward consolidation in the camp movement either through the combination of two or more hitherto separate camps or through the establishment of chains of camps.

Camping has become a profitable industry, contributing to the development of remote sections of the country, adding to the demand for roads and roadside advertising. It has grown to the point where it has been subjected to government regulations as well as government promotion. There is every likelihood that it will remain one of the important forms of recreation and amusement of the modern urban world.

HENRY M. BUSCH

See: RECREATION; PARKS; AUTOMOBILE INDUSTRY; BOYS' AND GIRLS' CLUBS; YOUTH MOVEMENTS; URBANIZATION; MOBILITY, SOCIAL.

Consult: There is no adequate general discussion of camping nor is any serious study of tourist camping available. There are a few partial treatments of organized camping which although they are written for the instruction of camper or camp leader throw some light on the social problems involved. See especially: Playground and Recreation Association of America, *Camping Out* (New York 1924); Dimock, H. S., and Hendry, C. E., *Camping and Character* (New York 1929); Gibson, H. W., *Camp Management* (Cambridge, Mass. 1923); Mason, Bernard S., *Camping and Education* (New York 1930).

CAMPOMANES, PEDRO RODRIGUEZ, CONDE DE (1723-1803), Spanish economist and statesman. He played a prominent part in the eighteenth century movement for the social and economic regeneration of Spain. From 1755 to 1791 he served successively as general director of the postal service, secretary of the treasury and president of the Royal Council of Castile.

By means of education, protective laws and the founding of model establishments he did much to develop commerce and manufacture.

In his *Tratado de la regala de amortización* (Madrid 1765) Campomanes demonstrated by historical and economic arguments the right of the state to interfere with the unconditional transfer of church or other real property and with mortmain in general. He campaigned with some success against the economic power of the church and supported the law of 1763 prohibiting conveyances to the church. His *Discurso sobre la educación popular de los artesanos y su fomento* (5 pts., Madrid 1775-77) is concerned with the industrial situation and the guild system of Spain. Campomanes was largely responsible for the legislation directed against the guilds facilitating apprenticeship and favoring independent artisans. In the *Memorial ajustado del . . . humrado concejo de la Mesta* (Madrid 1783) he explained the grazing privileges of La Mesta, the powerful guild of sheep raisers, and the difficulties that these privileges created for Spanish agriculture. He dealt a final blow to the power of the Mesta and aided agriculture by reducing taxes and allowing free traffic in grain. In the first, fourth and fifth letters of his *Cartas político-económicas* (Madrid 1878, written from 1787 to 1790) Campomanes summarized his views. His economic-social concept of the state stands out in contrast with the formal, legalistic conception of constitutionalism prevalent in the nineteenth century. He proposed that the government should reduce privilege, attend to the national administration and cultivate domestic economic resources rather than depend upon the colonies. Holding economic theories similar to those of the physiocrats he advocated a total reorganization of taxation in order to encourage trade and industry. Public income should be reduced and taxation should be of three kinds: progressive income taxes paid by all for the benefit of the crown; taxes not on property but on products; and luxury taxes.

CANALEJAS Y MENDEZ, JOSÉ (1854-1912), Spanish statesman. Born in Ferrol, he graduated from the University of Madrid and

soon afterward manifested strong radical tendencies. He was elected to the Cortes in 1881; seven years later he was appointed minister of justice and in 1894-95 minister of finance. Canalejas is the Spanish statesman most closely identified with socialism of the chair. He was responsible not only for the theoretical statement that "the liberal party should adopt the socialist viewpoint" but also for initiating the project of the labor institute. In December, 1901, he published in the review *Nuestro tiempo* a program of government in which he advocated labor contracts, minimum wage laws, social insurance, arbitration tribunals for social problems and laws for the protection of women and children. He proposed likewise the abolition of the consumers' tax, which was an indirect tax on commodities. As president of the Academia de Jurisprudencia he defended the reform of contract law in the civil code and its transmutation into social law. His campaign against latifundia and clericalism aroused public opinion in his favor. He was appointed president of the council February 9, 1910, and undertook the task of limiting the number of privileged religious orders by subjecting them to the general law governing associations and by prohibiting meetings of any group otherwise constituted. He issued an order permitting all religious cults to use outside signs on church façades, as well as an order allowing all except the military to substitute a promise for an oath. The result of this anti-clerical legislation was a suspension of relations with the Vatican. He quelled the railroad strike of 1912 by the effective though questionable device of mobilizing under military orders all railroad hands whose ages made them liable to service and by forcing them with threats of military punishment to return to work. This aroused the deep seated animosity of the working class. Canalejas was assassinated in Madrid on November 12, 1912, at the hands of an anarchist.

CANARD, NICOLAS FRANÇOIS (c.1750-1833), French economist. In 1801 a prize offered by L'Institut National for the best discussion of the doctrine of the single tax was won by Canard's *Principes d'économie politique* (Paris

1801), which also brought him fame as the author of the diffusion theory of taxation. He held that there is not only a natural labor—that is, labor necessary to sustain existence—but that there is also what he called acquired labor, as well as superfluous labor. These are the foundation of all surpluses or rents: *rente foncière*, the result of the fixed labor applied to land or industry; *rente industrielle*, the result of the *travail appris* in industry; and *rente mobilière*, the result of the *travail superflu* in commerce. All taxes must be paid from one of these three rents, since a tax can never remain on the *travail naturel* which is necessary to existence. The mutual struggle of individuals to secure the greatest surplus results in a balance or equilibrium, and all taxes are shifted because they disturb the equilibrium between the rents. There can be no new equilibrium until every buyer and seller bears an equal share of the burden. Canard likened the circulation of goods to a series of communicating tubes. No matter how much water is poured in or out of any tube it will seek its level by distributing itself proportionally to the diameter of each tube. All taxes, therefore, are ultimately borne equally by every one, which is the same thing as saying that they are ultimately borne by no one. In the meantime, however, while the new equilibrium is being reached, there is friction which may cause serious trouble. Canard therefore concluded that "every old tax is good, every new tax is bad." He was opposed to the French *octroi*, as well as to the new tax on the doors and windows, and his belief in the diffusion theory led him to suggest that these be replaced by a salt tax levied on the producer.

Canard was the author of a *Mémoire sur les causes qui produisent la stagnation et le décroissement du commerce en France, et qui tendent à anéantir l'industrie commerciale* (Paris 1826), in which he objected to the commercial treaties with England and the United States. He wrote also on criminal procedure, mathematics and meteorology.

CANDY AND CONFECTIONERY. See FOOD INDUSTRIES.

CANGA ARGÜELLES, JOSÉ, CONDE DE (1770-1843), Spanish statesman and writer on public finance. He became minister of finance in

1820. In 1823, when the constitutional government of Spain fell, he fled to England where he published *Elementos de la ciencia de hacienda* (London 1825), a discussion of the principles of public finance and their application to Spain. His *Diccionario de hacienda* (5 vols., London 1826-27; 2nd ed. in 2 vols., Madrid 1833-34) is a notable work containing various memoirs by the author and by other authorities on public finance. It furnishes a wealth of valuable information on Spanish and colonial economy and makes it possible to trace the evolution of public finance in Spain after 1700.

From the beginning of his ministerial career Canga Argüelles tried to reestablish the borrowing power of the government, which had declined because of the magnitude of the outstanding obligations and the failure to recognize the debts of the former government. He advocated a redistribution of the sales taxes in order to allocate some groups of them to the amortization of the debt. In his *Memoria sobre el crédito público* (Madrid 1820) he also proposed to dedicate to the same purpose a considerable portion of the church property. His intention was to reorganize the loan policy of the government so as to make public credit an instrument capable of serving the treasury in emergencies, but he witnessed only the partial realization of his plans. Some of the measures he proposed went into effect when entails were abolished.

FERNANDO DE LOS RÍOS

CANNIBALISM. The word cannibal dates from the discovery of the New World. When the Spaniards discovered the Antilles they visited the natives of the Bahamas. These people went man hunting in fleets, and were said to have broiled and eaten all male prisoners. In the native language *carib* meant a valiant man, and Columbus heard these natives described as *cambales* and again as *caribales*. Subsequently the word cannibal has been used to cover all anthropophagites.

According to Sumner and others cannibalism dates from the earliest known existence of man on earth, and it is reasonable to believe it a custom which all peoples have practised. A distribution chart (Loeb) including both prehistoric and recent examples supports this statement and indicates that human flesh was either habitually or periodically consumed by certain peoples of all continents and island areas. While it has not been definitely proved that Neandertal man was cannibalistic a very good case has been made for

the anthropophagy of Cro-Magnon. In certain burial caves left in Belgium by this early race human bones have been found which, like a number of the animal remains which lay near by, seem to have been the remains of a feast or merely "kitchen refuse."

None of the causes assigned for the practise of cannibalism among primitive peoples is entirely conclusive. Each has rested upon some environmental or psychological factor which "drove" the savage to consume human flesh; yet each could have been at best merely local in its application. The most frequently advanced causes have been lack of food or of larger animals, revenge upon tribal enemies, craving for salt and magical and religious beliefs.

It was formerly thought that lack of food drove the savage to cannibalism. At the time of post-Columbian discoveries, however, cannibalism in its extreme forms was almost universal in the tropics, where an abundance of food existed. Later ethnographers, aware of the absence of large mammals on the South Sea islands and on the continent of Australia, decided that the savage was necessarily cannibalistic because of this lack of warm blooded animal food. But Livingstone and later explorers found cannibalism in interior parts of Africa which were rich in both animal and farinaceous foods. It has been argued further that the Aztecs were cannibals because they had no animal larger than the dog, and that the Incas were not because they possessed the llama. Yet the Toltecs, the race to which the Aztecs owed most of their culture, were devoid of cannibalism, while the native tribes subjected by the Incas were cannibalistic. Revenge was the ruling motive for consuming one's enemy among the Fijians, the Maori and the Marquesan islanders. On the other hand in parts of New Guinea human flesh was often eaten because its flavor was thought superior to that of pork. Sir Harry Johnston has suggested that cannibalism may have arisen in Africa through a craving for salt, but among the man eating natives of the South Seas there is no scarcity of this commodity. Koch, from a comparative investigation of cannibalism among South American Indians, concluded that primitive ideas of magic drove these indigenes to cannibalism. Again, this explanation would seem to prove unsatisfactory in the case of people like the Fans of equatorial west Africa, who sold human flesh in their "butcher shops."

Back of many arguments lies the implied assumption that cannibalism is a violation either

of man's natural instincts or, at least, of his better judgment. But there is no more reason to suppose that man has an instinctive horror of eating human flesh than that he has an instinctive horror of incest. Brehm in his *Thierleben* has given many examples of animals eating members of their own species, and even McDougall has never claimed that man has more instincts than the animals. If man possessed an instinctive aversion to cannibalism it would be impossible to commit the "crime" unknowingly. Yet many white travelers have done this very thing, and have been filled with remorse only upon discovery of their error. The soldiers of Cieza de León, for example, pilfered a pot of "rabbit" flesh from the Amazonian Indians, and it was only after they had eaten their fill that they became aware of the true nature of their repast.

It is difficult for an anthropologist to believe that where primitive groups have given up cannibalism they have done so from rational motives. Frazer has shown in the *Golden Bough* that the primitives fail to make any sharp distinction between men and animals, and this is also the observation of many field workers who have worked in the field of American Indian mythology. Not only has cannibalism not seemed necessarily wrong to savages, but even some European philosophers have made certain satirical comparisons between cannibalism and some practices of civilized peoples. Montaigne quoted the stoic leaders to the effect that it was more humane to eat a victim than to torture him to death, and Voltaire cynically queried the utility of civilized warfare in which the bodies were left as a repast for the crows and ravens.

The tabu on human flesh is a food tabu comparable to the Semitic tabu of pork. Although the exact origins of such tabus are obscure it is certain that they are produced by ideas of religion and magic. The waning of cannibalism must thus have been due to ghost fear. A survey of regions in which the custom was practised at the time these regions were discovered shows that religious restrictions usually surrounded the eating of human flesh, which was considered either unclean or sacred.

The same considerations which put an end to cannibalism in some quarters may have prolonged it in others. If it was dangerous to incur the wrath of a hostile ghost by consuming a human being, it was also wise to get mana in this manner. If man became superior to the animals in degree of sacredness, then it was better ritu-

ally to partake of the flesh and blood of the human god than of an animal.

In general, except in the case of the Pygmies, the Veddahs and the Tasmanians, cannibalism has survived until modern times almost exclusively among black skinned peoples and some Mongoloids of North and South America. It is significant that these are the same groups who preserved longest the archaic traits of tribal initiation. These are also the peoples marginal to the culture waves of higher civilizations. Outside of these groups it may be noted that certain Polynesians, mentioned above, and the Batakas among the Malaysians also practised cannibalism upon their enemies and prisoners of war.

CANNING, GEORGE (1770-1827), British statesman and diplomat. Canning was born in London, the son of a barrister. He entered Parliament in 1794 as a disciple of Pitt, held office during the war, and won European fame as foreign secretary (1822-27) and finally as prime minister. A Conservative looking more to commercial than to landed interests and a convinced believer in constitutional monarchy, he based foreign policy upon national expediency alone—with results as profitable to rising nationalism as they were discouraging to Metternich's "good Europeans." He emphasized his predecessor's dislike of joint intervention in the internal affairs of smaller states, but went much further by his public ridicule of the European Concert itself and of the congresses which were its means of action. His preference for isolated action appears in the dictum: "For *Alliance*, read *England*." Faced by revolutions of different

origins and varying respectability he refused to intervene on behalf of "legitimate" governments, and so earned a scarcely coveted reputation as patron of nationalities and even of radical constitutions. In Greece he intervened at last in 1826, but on behalf of the insurgents and with Russia and France alone. Already the Concert had foundered upon the rocks of French intervention in Spain and the rumored threat of a reconquest for Spain of South America, a market newly opened to English trade. Against this danger Canning looked to the United States and partly inspired the proclamation of the Monroe Doctrine, which was followed by English recognition of the South American republics. In this sense he afterwards boasted, "I called the New World into existence to redress the balance of the Old." Disliked by both parties at home, he left some devoted followers and a strong tradition of "splendid isolation" in foreign policy, which lasted until the end of the century.

CANNING, STRATFORD, VISCOUNT STRATFORD DE REDCLIFFE (1786-1880), British diplomat. Stratford Canning obtained a post in the British Foreign Office in 1807 when his cousin, George Canning, became secretary of state for foreign affairs. The following year he became secretary in the British embassy at Constantinople, and after the retirement in 1810 of his chief, Sir Robert Adair, Canning took practically sole charge of the embassy. It now fell to him to conduct negotiations, leading up to the Peace of Bucharest (1812), which brought to an end the war between Russia and Turkey and enabled Alexander I of Russia to concentrate upon meeting the invasion of Napoleon. Thus Canning not only contributed to the fall of the Napoleonic empire but also laid the foundations of British influence at the Porte. In 1814 Canning was British minister to Switzerland and helped to draft the Swiss constitution. As minister at Washington (1820-24) he proved friendly to the United States in spite of some passages at arms with John Quincy Adams. His mission to Constantinople in 1825 and to Corfu in 1828 contributed to the independence of Greece. Between 1828 and 1841 he was almost

continuously a member of the House of Commons; in 1842 he was appointed ambassador to Turkey. Here he made a position such as no ambassador had previously held. Turkish ministers frequently met in his dining room, and his advice was taken on matters of high policy. It was owing to his firmness that the Turks refused the demands of Russia for a protectorate over the sultan's Greek church subjects, which Canning thought would be fatal to Turkish independence. The Crimean War, which followed, is the sole exception to the success of Canning's efforts to adjust international difficulties and to make or keep peace. Canning was created Viscount Stratford de Redcliffe in 1852. His *The Eastern Question* (London 1881) is a collection of articles written after his retirement from the diplomatic service in 1858. A most illuminating account of the conditions of the Turkish Empire and suggestions for a consistent British policy are to be found in Canning's great dispatch of August 9, 1832 (Great Britain, Foreign Office, Foreign Office Records, *Turkey*, vol. ccxi).

R. B. MOWAT

Consult: Lane-Poole, S., *The Life of the Right Honorable Stratford Canning, Viscount Stratford de Redcliffe*, 2 vols. (London 1888).

CANNING INDUSTRY. The canning industry owes its origin to the fact that foods sterilized by heat and hermetically sealed will retain their quality for months and even years. Systematic food preservation by drying, smoking, salting and other household methods is as old as civilization, but the art of canning is of comparatively recent origin. A Frenchman, Nicholas Appert (1750-1841), was the first to carry on commercial canning and also the first to write a systematic treatise on the subject (1810). During his early experiments Appert enclosed food in glass jars, corked them with great care, submerged them in water which was gradually raised to the boiling point and boiled them "for more or less time according to the nature of the food"—a method still used successfully in household canning for fruits and acid vegetables. Later he experimented with tin and with wrought iron cans, tin plated.

In its early years the canning industry was carried on by simple hand processes. The cans used by Appert were made by hand in his own factory, and other canners followed his example until about 1885, when several inventions made possible machine made cans, and can making became an industry by itself. Successive inven-

tions have also decreased the amount of work to be done by hand in the canning process and increased the number of foods which can be canned. Milk presented peculiar problems which were solved by Gail Borden in 1856. In the early eighties Welcolm Sprague invented a continuous chain feed machine for removing the kernels of sugar corn from the cob. The first practical machine for shelling peas from the pod was invented in 1885, and in 1893 E. P. Scott patented a machine which picked the pods from the vines and shelled them at the same time. The canning of salmon in the northwest was at first carried on very successfully with Chinese labor and very little machinery, but when this source of labor supply was cut off and the industry continued to grow, machines began to be introduced. Finally in 1903 a machine was perfected which handled the entire process of the preparation of the fish for the can, and it came to be known as the "iron Chink." There are now also machines for washing fruits and vegetables, and lye peeling has quite generally done away with hand peeling.

Since merely raising the food to the boiling point was not enough to destroy all bacteria, it was not until Pasteur's work with the bacteria of fermentation that the industry was placed on a firmer scientific basis. The most serious technological problem in the industry has latterly been that of dealing with *Bacillus botulinus*, the spores of which are destroyed at the temperature of boiling water only after long continued heating, especially if the food being canned is nearly neutral or only very slightly acid. The high temperatures made possible by the retorts of commercial canners and by the use of the pressure cooker in home canning have greatly reduced the danger of botulism in this country. While the disease is rare, the percentage of fatality is very high.

The canning industry has spread to practically every country in the world. Nicholas Appert went to London in 1814 to widen the market for his canned goods, but succeeded instead in stimulating many imitators of his methods. Although English as well as French canners had to struggle with very serious technical difficulties in the early years of the nineteenth century, a very prosperous canning industry grew up in both countries. Neither of these countries has, however, the advantage of the very large food production in proportion to population which makes the canning industry so important in the United States; in fact the United Kingdom has

become by far the largest importer of canned goods in the world. Figures for a comparison of the output of canned goods in the various countries are difficult to obtain. Export trade statistics, however, shed some light on the relationship of the volume of production to that of home consumption with regard to various types of canned goods. They show that the canned foods now exported in the largest quantities from the United States are fruits, fish, milk and vegetables. Canned beef, once a valuable export from the United States, has greatly declined in importance with the growth of population, the increase in domestic demand for fresh meat and the decline in ranges available for cattle. Meanwhile, shipments of canned beef from Argentina and Uruguay (where production is largely financed by North American capital) have greatly increased. The foreign trade in canned vegetables is much less important than that in canned fruits because of the greater bulk of canned vegetables in relation to their value. France has a valuable export trade in high grade canned vegetables, and Italy in canned tomatoes and tomato paste. Canned fish is exported in large quantities from the United States, Russia, Canada, Norway, Portugal, France, Spain and Japan; canned milk from the Netherlands, Switzerland, Denmark, the United States and Canada; canned and preserved fruits from the United States, Italy, the Netherlands, England, France, Australia and the Straits Settlements, where a large pineapple industry is developing.

Commercial canning in the United States is said to have begun in 1821 with a Boston cannery operated by William Underwood, an Englishman who had served an apprenticeship in pickling and preserving in London. It was in Baltimore, however, that the industry gained its first real foothold. Oyster canning was carried on there as early as about 1840, as was also the canning of tomatoes and fruits. Until about 1860, however, the industry was greatly handicapped by a lack of scientific understanding of sterilization processes and by a lack of demand for canned foods. The federal army used large quantities of canned foods during the Civil War, and the industry grew rapidly in the years directly following the war, partly because of an increased understanding of the canning process and partly because of the trend of population toward the cities.

American census statistics on the canning industry date from the year 1870, and the following table indicates the growth of the industry

from 1870 to 1920 (separate figures not available for early years, except in reference to fruits and vegetables):

NUMBER OF ESTABLISHMENTS ENGAGED IN CANNING
IN THE UNITED STATES

DECENNIAL YEAR	FRUITS AND VEGETABLES	SERVIS AND SAUSAGES	FISH AND OYSTERS	CON- DENSED MILK
1870	97			
1880	411	109		
1890	886	316	126	
1900	1813	424	369	50
1910	2789	580	398	136
1920	3082	723	475	401

Meat canning in the United States is an incidental activity of slaughtering establishments, and statistics on the number of establishments canning meat are not available. In comparison with the other products of the slaughtering and meat packing industries, canned meat is relatively of little importance. The value of all the products of this industry was \$3,057,216,000 in 1927, while that of canned meat and canned sausage was only \$27,824,000. The value of canned meats and canned sausage imported into the United States that year was \$4,311,000. Vegetables and soups canned in the United States in 1927 were valued at \$234,260,000, canned milk at \$167,850,000, canned fruits at \$101,731,000 and canned fish and oysters at \$51,090,000. Canning on the west coast of the United States began in 1856, and California soon developed an export trade in canned fruits. In 1864 a salmon cannery was established on the Sacramento River, but Washington and Oregon were found to provide more profitable fishing grounds and the salmon canning industry became established upon the Columbia River and Puget Sound. The salmon of this region have become increasingly scarce, however, and in 1928 Alaska provided over 85 percent of the canned salmon output of the nation.

The canning industry is not a large scale industry. Though in the United States several well known corporations organized on a national scale are engaged in canning, they can scarcely be considered typical of the industry. The desirability of locating plants close to raw materials, which because of their perishable nature cannot be transported over long distances, necessitates decentralization of operation. There is a well defined tendency also toward decentralization of management, due largely to the seasonal character of the industry, the dependence

upon uncertain weather conditions and the need for driving sharp bargains with many individual farmers. The flexibility of the industry is such that there are many small canneries which operate only if there is an abundant crop in their vicinity and only a small carry over of the canned product from the previous year.

This instability the canning industry derives largely from its close dependence upon agriculture. It exerts in turn a certain standardizing effect upon the portions of agriculture with which it comes into contact. In many sections of the country the farmer, though uncertain of his crop, becomes certain of his market by contracting with the canner for the disposal of his crop before he even undertakes planting. His activities are further controlled by the canner's careful selection of seed and instructions with respect to methods of growing and harvesting.

While the canner in getting his raw materials from the farmers comes into contact with numerous individual enterprises, his other major contact is with a business unit generally much larger than his own. The industry of manufacturing cans is typically large scale. In the United States two companies dominate the field, the larger of which has an output four times that of the second. In England 60 percent of the production comes from one company. Each of the American corporations has dozens of plants scattered over large areas, but centralization of management has been feasible because of the complete standardization of operations and the steady source of raw materials.

The marketing of canned goods has usually been relatively stable. The canner has been favored by an unusually large percentage of advance orders as compared with other types of manufacturing. In recent years, however, the trend of advance orders has been definitely downward and the number of small orders has been increasing. This recent tendency toward hand to mouth buying has been in part compensated by the stabilizing effect of the large orders from chain stores and purchasing groups of independent retailers.

Until the last decade canned foods reached the consumer only after passing through a marketing process involving four different groups: canners, brokers, wholesalers and retailers. With the transformation in marketing methods wrought by the development of the chain store and of group buying the retailer has frequently come to buy direct from the canner

and to take over the warehousing of a considerable part of the pack. This practise has reduced the cost of marketing but the extent of its influence upon retail prices throughout the country is difficult to estimate.

Canned foods come to the consumer under a multiplicity of brand names and trademarks, some emanating from the manufacturer, some from the wholesaler. Grades of canned goods have been distinguished by a great variety of vague descriptions. Systematic grading was begun through the "Service and Regulatory Announcements" connected with the administration of the Federal Food and Drugs Act, by which minimum standards for health were defined and proper methods for labeling the weight of the food content of cans were established. Methods of grading quality are gradually being worked out. Standards for such grade designations as "fancy," "choice," "standard" and "second" have been set up for a number of canned fruits by several canners' associations. Standards for canned vegetables are now being developed by the Federal Bureau of Agricultural Economics at the request of the vegetable canners who desire to store their products in warehouses licensed under the United States Warehouse Act and to borrow money on goods so stored.

Attempts to regulate the canning industry have taken two directions, regulation of sanitation and regulation of the conditions under which wage earners are employed. Federal inspection of meat canning establishments producing goods to be used in interstate commerce has been very successful in raising the standards of sanitation. The federal government does not inspect the canneries which put up fruits and vegetables, but contents itself with detecting sanitary violations in the products of the canneries, under the authority of the Federal Food and Drugs Act. Several of the states maintain sanitary inspection of canneries, though the fact that many small establishments operate for only a short period during the year makes complete inspection difficult. The National Canners' Association has drawn up a statement of sanitary precautions and of working conditions which is intended to guide the members of the association, but the rules laid down are not binding on the members. Because of its short season and the perishability of the product handled, the canning industry was not included in the early state laws regulating hours and wages. In recent years some states have begun to regulate hours and

wages of women and minors in the industry. California and Wisconsin have been particularly successful in the regulation of wages and hours of work. California penalizes the employer for long hours by requiring higher rates of pay after eight hours have been completed in one day and double rates for every hour after twelve.

The seasonal character of the canning industry and its localization near the sources of raw materials make difficult the problem of an adequate labor supply. Since little skill is required of workers and much of the work is easy if done under proper conditions, the employment of women and children in canning factories has been the rule since the beginning. With the introduction of machinery, however, the employment of children in canning factories has declined in recent years. According to figures from the Federal Census of Manufactures, the proportion of wage earners under sixteen employed in canning factories dropped from 8 percent in 1899 and 7 percent in 1909 to 2 percent in 1919. The Federal Child Labor Tax Law was in effect in 1919, and the extent to which it may have brought about a reduction in the number of children reported as working in canneries in that year cannot be determined. A recent (1930) report by the United States Children's Bureau shows that large numbers of children are still being employed in canning factories, many of them working long hours under unsanitary conditions. Of 560 fruit and vegetable canneries visited, employing 56,828 workers in Washington, Delaware, Indiana, Maryland, Michigan, New York and Wisconsin during the seasons of 1923, 1925 and 1926, 80 percent were employing children under sixteen years. A large proportion of very young children, some under twelve, were found in some states. Tomato canneries employ many more young children than any other kind. Nearly half the children in all the canneries visited by representatives of the Children's Bureau worked as tomato peelers. This work is light except in poorly equipped canneries, in which the peelers are required to lift pails of waste from table to floor or from one table to another. In most of the states covered by the bureau study the children's working day was very often as long as that of adults. The Children's Bureau survey shows that practically all the canneries in Michigan, Indiana and New York furnished some seats for their women workers, but that many girls under sixteen in canneries in these states were standing at their work all day long. Conditions in Delaware and

Maryland were conspicuously bad. "More than two thirds of the Delaware canneries and about three fourths of the Maryland canneries provide no seats for any of their women workers, not even boxes, crates or overturned pails." In the fish canneries children's work was more difficult than in the fruit canneries. The hours were also more irregular because "the catch cannot be regulated and it is considered impossible to 'hold over' fish from day to day."

Many of the smaller canneries draw their labor supply from nearby farms and towns, but the necessity for canning perishable products before they spoil requires a large labor force for a short time, and in some states the cannery recruits family labor from outside the community. Nearly 6000 migratory persons, almost half of whom were children under sixteen, were living in 126 of the 143 cannery labor camps included in the Delaware and Maryland surveys made by the Children's Bureau. The care of children too young to work in cannery labor camps is a problem which has received little attention. Not only are they subjected to unsanitary conditions and permitted a carelessness about school attendance, but unsupervised children are less safe in the cannery than in the agricultural labor camps because the camps are usually near railroad tracks and because the children are likely to get into the cannery workrooms where they are in danger from unguarded machinery. Recreation centers and day nurseries have been established in cannery camps in a few places in Maryland, Delaware, New Jersey, Ohio and on the Pacific coast, either by the cannery themselves or by welfare organizations.

The extent of home canning throughout the United States cannot even be estimated. Until 1910 home canning was done very largely by the open kettle method, which frequently did not result in a sterile product. In that year an attempt by the General Education Board to improve home conditions in the South included the organization of clubs for tomato canning. The Home Demonstration work begun under the Smith Lever Act of 1914 and carried on by extension workers of the Department of Agriculture and state colleges continued to support the tomato canning clubs, partly because the leaders in this type of education felt the urgent need for increasing the money incomes of the club members, and partly because with this incentive girls and women were learning better ways of canning for their own families. The need for conserving food products during the war

period led to a great increase in the number of persons who taught canning methods to rural and city housewives, and the amount of home canning probably increased greatly during that period. Since the war several forces have been operative in qualifying this trend, notably the increasing consumption of fresh vegetables and the improvement in their marketing.

The effect of the increase in canning upon food consumption in the United States cannot be accurately measured. Analyses of family diets early in this century showed that city diets in the United States were on the average deficient in mineral salts obtainable from fruits and vegetables. A vigorous educational campaign and improvement in the commercial production and marketing methods resulted in an increased consumption of fruits and vegetables. During the war period the campaign for economy in meat consumption and the high price of meat combined to accelerate this change in the American diet. No quantitative figures are available to measure changes in the amount of fruits and vegetables consumed in the last century, but three successive studies of expenditures by American wage earning families carried on by the United States Department of Labor indicate that the percentage of food expenditures devoted to fruits and vegetables has materially increased during the last forty years. A study of 1917 shows that about one quarter of the vegetable expenditures and one fifth of the fruit expenditures went to purchase canned foods. The value of the annual per capita consumption of commercially canned fruits and vegetables in the United States increased 180 per cent from 1899 to 1927 (the 1899 figures having been adjusted to the 1927 price level), from \$1.72 per capita per year in 1899 to \$4.81 per capita per year in 1927. Percentages of increase for different kinds of products (all based on the adjusted value of annual consumption per capita) are as follows: canned milk, 368 percent; canned fruits, 162 percent; canned vegetables, 148 percent; canned fish and oysters, 125 percent; canned meat, 120 percent. Studies of food consumed by college students in 1893 and 1926 show a decrease in fresh fruits, an increase in canned fruits, an increase in fresh vegetables and a decrease in canned vegetables.

The consumption of canned foods, while its outward importance lies in its furnishing the basis of an industry, becomes in the context of modern social changes indicative of a new way of life. It spans the severance of the household from

the garden plot and the fruit trees which formerly conditioned its self-sufficiency. It represents one of the most important steps yet taken toward the emancipation of women from household drudgery, and thus becomes one of the significant items in the industrial revolution of the home. While as a result of the development of refrigeration it has ceased to be exclusively important in food preservation, it has by packaging ready-to-eat cooking ministered to and been aided by the heightened mobility of life, especially in the United States. Its standardizing effect upon eating habits and eating tastes, while too elusive and too close to us to be easily assayed, is certainly appreciable. Most significantly it has established a new set of consumption habits less dependent than formerly upon the immediate variations in the sources of food supply, and has to that extent intensified the primarily urban character of modern life.

CANNON, JOSEPH GURNEY (1836-1926), American congressional leader. At the age of twenty-two Cannon began the practise of law in Illinois and his first public office was that of state's attorney. He was elected to Congress in 1872 and with the exception of two terms he served continuously until his retirement in

March, 1923. Always a "regular" Republican, able and resourceful in parliamentary strategy but ruthless and with a strain of coarseness in his nature, Cannon early took his place as one of the leaders of the House. From 1883 to 1889 he and Thomas B. Reed were minority members of the Committee on Rules. In 1889 he was an unsuccessful candidate for the speakership. He headed the powerful Committee on Appropriations from 1897 to 1903 and was elected speaker in 1901. In this office he was far more powerful and dictatorial than any of his predecessors had been. In fact he always maintained that he considered the speakership of the House a more powerful and attractive office than the presidency itself. His principal weapons were the power of appointment to committees and of recognition of members from the floor. He could make or mar the career of a newly elected representative. As a member of the Committee on Rules he was able substantially to determine the business that the House would consider. This form of dominance of the speaker over the House became so identified with Cannon that it was called Cannonism. After 1907 there were signs of revolt and in March, 1910, a coalition of Democrats and insurgent Republicans was successful in forcing far reaching changes of the rules. The speaker was excluded from membership on the Committee on Rules, which along with the legislative committees was thereafter to be elected by the House. As a result the speaker became more the servant than the master of the House. His leadership was put in commission. The coalition, however, was unable to declare the speakership vacant and Cannon served until the Democrats gained control of the House and elected their own speaker in March, 1911. Thereafter the ex-speaker was a representative of steadily dwindling influence.

CANON LAW. The law of the Roman Catholic church consists fundamentally of the *jus divinum*, the *jus canonicum* and that part of the

entire body of the law which is neither divine nor canonical.

The *jus divinum* is contained in the Holy Scripture and in *traditio divina*; and it is immutable. *Traditio divina* consists of those oral ordinances of Christ which, although they were not embodied in Holy Writ, are proved to have been transmitted to the church through the concordance of the church fathers. The *jus divinum* has given its spirit and much of its substance to the *jus canonicum*. Not only are the sacraments based upon it but the constitution of the church, including the episcopate and the primacy of the pope, is largely derived from its teachings. Religious, moral and theological ideas embodied in the *jus divinum*, such as the conception of sin, have been transformed into rules of the *jus canonicum* by the legislation of councils and popes. *Jus divinum* suffuses the entire body of *jus canonicum* and gives it life.

In early mediæval times the legislation of councils and popes was known as *jus canonicum*. The division of the church into the Roman and the Greek Catholic churches meant, however, a fundamental division of the law into the Roman and the Greek canon law; and, while both churches possess the earlier sources of canon law in common, the historic development of the two separate churches has resulted in basic differences between the Latin law of the West and the Greek law of the East. In the West the Latin *jus canonicum*, which alone concerns us here, was largely composed of conciliar canons contained in the Greek collections; but this Greek material was continuously supplemented by Latin elements, chiefly the canons of occumenical and local councils and papal decretals. The process of unifying the western law, furthered by the diffusion of canonical collections, notably the *Dionysio-Hadriana*, the *Hispana* and the *False Decretals*, was accompanied by its systematization. By the spread of these regional collections many local canons were added to the growing body of the *jus commune*.

The history of the sources of canon law during the period immediately prior to Gratian's time is intimately interwoven with the reform movement within the church. The reformers were chiefly interested in the primacy of the Apostolic See, the validity of the sacraments, the coercive power of the church, investiture and simony; and upon these and other important subjects the several types of canonical collections, most of which were national or regional in character, contained numerous contradictions and hence

introduced confusion in the substance and administration of the law. In seeking to achieve their main purposes, such as the primacy of the pope and the coercive power of the church, the reformers were anxious to restore the former discipline; and accordingly in their work of revising the collections they not only appealed to earlier canons which possessed the character of universality but they also sought to suppress texts of German or Celtic origin. Not one of the numerous collections of the time, not even the *Decretum* of Burchard of Worms (c. 1012) nor that of Yves of Chartres (c. 1095), was regarded as adequate by the reforming party.

Although in fact much confusion in the sources still remained, a new method of interpretation began to come into use at the end of the eleventh century by which precept was separated from counsel and principles of eternal validity were distinguished from those variable elements of the law which arose out of particular circumstances of time, place or persons. Abélard in his *Sic et non* extended the possibilities of this dialectical method of proving the relativity of rules and harmonizing contradictions; but it was Gratian who applied this new method for the first time to the whole enormous mass of diverse texts contained in the many current collections of canons. Gratian's work, produced at Bologna in the period of the revival of legal studies, proved to be so successful and so acceptable to the church that it became the foundation of the classic law.

The appearance of Gratian's *Concordantia discordantium canonum*, generally known as the *Decretum*, marks the beginning of that new epoch in the history of the canon law during which the *Corpus juris canonici* was gradually formed. As finally completed, at the end of a development which covered three and a half centuries, the *Corpus juris canonici* consists of two main parts. The first part, Gratian's *Decretum* (c. 1140), serves as the foundation. Based on earlier collections it is essentially a systematic treatise on the canon law in which the authorities are included; and although a private work, apparently produced under the strong influence of Abélard, it was soon treated as official and received formal recognition in Gregory IX's decretals. In the law schools it was used as the textbook in canon law, while in the hands of the canonists it was soon supplemented by a large body of glosses. During all succeeding centuries it has served as the foundation of the structure of *jus canonicum*, exerting a vast

influence on the study and spread of that system. The second part is composed of four collections of papal decretals: the Decretals of Gregory IX (1234), an official compilation or code of papal decretals issued after the completion of the *Decretum*, including those of Gregory himself, which is generally known as the "Extra" (*Decretales extra decretum vagantes*); Boniface VIII's *Liber sextus decretalium* (1298), a collection of decretals issued subsequent to the "Extra" and called *Sextus* because it was regarded as a continuation of the five books of the "Extra"; the *Clementinae*, a collection of decretals, including his own, which was originally published by Clement V (1313) and later recast and published by John XXII (1317); the *Extravagantes*, a private collection of decretals which was treated as if it were official and which consists of two parts, the *Extravagantes* of John XXII and the *Extravagantes communes*, including the decretals issued by various popes, after the publication of the *Sextus*, from Boniface VIII to Sixtus IV (died 1484).

The appearance of the *Decretum* gave to the study of canon law a new and vigorous life. It became a separate branch of legal science distinct from and yet closely related to the study both of civil law and of theology. The universities made *doctores decretorum* as well as *doctores legum*; and from the thirteenth century onwards an increasing number of jurists became *juris utriusque doctores*. While the civilians were known as the legists, the canonists were classed as decretists and decretalists. The decretists wrote glosses upon the *Decretum* either between the lines of the text (*glossae interlineares*) or upon its margin (*marginales*); and they composed fuller and more detailed explanations of the text (*apparatus*) as well as summaries of the contents of its several sections (*summae*) which were essentially systematic treatises. The decretalists followed methods similar to those of the decretists, but their treatment of the collections of decretals was fuller, freer and more fruitful than that given to the *Decretum*. Writings on the procedure of the ecclesiastical courts formed a special and important branch of canonistic literature.

The history of the Roman Catholic church in the modern epoch, since the Reformation, is reflected in the development of her legal system. While the *Corpus juris canonici*, as modified from time to time, has served as the basis of the legal system, the modern law embraces also that large body of legal rules and principles not included

in the *jus canonicum* which is known to jurists as "church law." The chief sources of the modern law, either as *jus canonicum* or as church law, are papal acts of legislation, known as *constitutiones* in distinction from mediaeval *decretales*, the legal provisions of the Council of Trent (1545-63) and the Vatican Council (1869-70), the decrees and decisions of the curial *congregationes* and the *concordata* concluded between the pope and territorial states. The new *Codex juris canonici*, one of the most important and successful codifications of our time, has been in force since 1918. Based on the *Corpus juris canonici* and the modern sources it has absorbed into the *jus canonicum* parts of the law hitherto known as "church law." While *jus canonicum* in the present day sense means the law contained in the *Codex*, this codification does not contain the entire law of the church; and the distinction therefore between *jus canonicum* and church law still persists. In general the liturgical laws, the law embodied in *concordata* and customary law form no part of *jus canonicum*.

While the constitutional law of the church, as embodied in *jus divinum* and the *Corpus juris canonici*, has been modified in the period since the Council of Trent, most of its mediaeval principles still persist. In the pope reside the supreme legislative, administrative and judicial powers over the whole church; and in his government of the church he is assisted by the Curia Romana, which in modern times is composed of cardinals, prelates and other officers. To the pope alone belongs the right to create *jus commune* and to grant dispensations and privileges; only the immutable *jus divinum* restricts his power. Bishops possess limited legislative and dispensing power. The exercise of the pope's judicial power is entrusted to tribunals which form a part of the Curia. Appeals from bishops' courts are taken to the tribunals of second instance, notably the courts of archbishops and metropolitans; while from these tribunals cases may be carried to the papal courts of appeal. In the later Middle Ages the most imposing of these papal courts was the Sacra Rota Romana; and especially in the fifteenth and sixteenth centuries it was viewed as *totius christiani orbis supremum tribunale*. The reorganization of the Curia by Sixtus V (1588) through the establishment of standing *congregationes*, some of which were invested with extensive judicial powers, resulted in a gradual decline in the importance of the Rota; but in our day, as part of the reorganization of the Curia by Pius X

(1908). the Rota has been brought back into prominence by being made a court of appeal in both civil and criminal cases. The *decisiones Rotae*, which cover a period of six centuries, form a most important source of our knowledge of the application and development of canon law by judicial practise.

The mediaeval *jus canonicum*, as finally embodied in the *Corpus juris canonici*, drew its substance not only from ecclesiastical sources, notably *jus divinum*, the customs and ideas of the clergy and *opinio doctorum*, but also from secular legal sources, chiefly Roman law, Germanic law and custom, mediaeval town law and feudal custom. In its main characteristics this mediaeval *jus canonicum* was the outgrowth of ecclesiastical policy. The church, regarding itself as the greatest of all the civilizing institutions of the world, undertook many of the social and economic tasks which in modern times have come within the competence of the state. The scope of ecclesiastical legislation and judicature was extended far beyond the range of purely ecclesiastical matters; and the *jus canonicum* included therefore many rules and principles which dealt with temporal subjects such as the oath, usury, prescription, contracts and international relations from the standpoint of the church. Not only the scope but also the general character of the *jus canonicum* was determined by the effort of the church to extend its sway over all the affairs of mediaeval society. Although that attempt was not in all respects successful, owing to the competition of other factors in mediaeval history such as the rise of the empire and of territorial monarchies, the spread of feudalism and the growth of towns, the *jus canonicum* was in fact the fundamental guaranty of law and order in mediaeval Europe. It represents, moreover, the effort of the church to enforce morality by legal means.

A survey of some of the salient features of the mediaeval canon law will serve to indicate the nature of that system and the reasons why it was able to exert so powerful an influence on the social, economic and legal development of Europe both in mediaeval and in modern times. While the canon law has failed to maintain its supremacy since the regulation of social and economic life has been taken over by the modern state, it still exerts through the spread of its ideas and principles to secular law a far reaching moral dominance over the social life of today.

The writings of the canonists based upon the texts of the *Corpus juris canonici* contain many

political and jurisprudential theories in regard to government, law, custom, justice, equity, property and many other topics of similar character; and these canonistic doctrines have exerted a widespread influence on thought. In the hands of the canonists many doctrines of the Roman classical jurists and the mediaeval civilians reached a fuller development. Gratian's identification of the *jus naturale* with the *jus divinum* is illustrative of this process of thought; while an even more striking example is the expansion by the canonists of the theory of the corporation which they found in the writings of the civilians. By introducing features derived from ecclesiastical and mediaeval institutions the canonists contributed to the idea of legal personality some of its most distinctive traits; and by this shaping of "the Romano-canonical theory of the corporation" they prepared the way for its profound influence on legal and political thought and for its adoption in mediaeval and modern systems of law.

The canon law of the Middle Ages exerted in fact a far reaching influence on all branches of secular law. Through the constitutional and administrative features of its law the church transmitted to mediaeval and modern times the Roman conception of government; and the monarchic constitution of the church, with its centralization of power in the papacy, has been the model which modern states have reproduced.

The criminal and disciplinary system of the church, which forms a most important part of canon law, rests in its origins on Christian conceptions of morality and sin; and while other features were gradually introduced it has never lost these early characteristics. In the beginning the church limited its jurisdiction to ecclesiastical delicts and in the main employed only ecclesiastical methods of discipline. In course of time, however, the church went beyond the purely ecclesiastical sphere and entered the domain of lay jurisdiction in criminal cases; and as an important aspect of its rise to a position of dominance in the mediaeval world it ultimately acquired a jurisdiction which was truly criminal in character and so extensive in scope that it materially curtailed the criminal jurisdiction of mediaeval territorial states. The church claimed that its courts had jurisdiction over all offenses of the clergy; but in respect to delicts of the laity it drew distinctions. In the case of all *delicta mere ecclesiastica*, offenses directed against the faith, the *cultus* and the constitution

of the church, notably heresy, schism, apostasy and simony, the church claimed jurisdiction even though most of these delicts were punished by the secular tribunals. While, under the title of sin, the church would have liked to bring all offenses into the scope of its jurisdiction, it was unable to carry out so sweeping a policy and developed therefore the notion of *delicta mixta*, offenses which, although not directly aimed against the church, indirectly placed it in danger. In respect of this numerous class of delicts, which included perjury, blasphemy, sacrilege, sorcery, usury as well as offenses directed against life and limb and those caused by carnal lust, the church acquiesced in a compromise; in case the state punished, ecclesiastical jurisdiction was competent only in the sphere of the *forum internum*, but whenever the state did not punish, the church exacted the punishments recognized by secular law. In the case of *delicta civilia* the church entered no claim and admitted the competence of the secular tribunals.

In consonance with the view that delicts were sins the church based its system of punishments upon two ideas, the reclamation and cure of the sinner and the expiation of the unrighteous and wrongful act. As it stressed the one or the other of these two conceptions, the church inflicted either *poenae medicinales* or *poenae vindicativae*. The former were *excommunicatio*, *interdictum* and *suspensio*; while the latter included not only punishments of a temporal character, such as banishment, imprisonment and chastisement, which were inflicted upon clergy and laity alike, but also special kinds of punishment in the case of the clergy, such as *privatio beneficii*, *depositio* and *degradatio*. In general the ecclesiastical tribunals did not make use of either death or mutilation as punishments; nor did they permit corporal punishment of a kind which would result in loss of blood.

Influenced both by Roman law and Germanic custom the early canon law recognized only the accusatory system in the criminal procedure of the ecclesiastical courts; but during the later Middle Ages the church developed its famous inquisitorial system. The *processus per inquisitionem*, which in its beginnings was essentially an official prosecution by the judge, wherein he proceeded *ex mero officio*, was introduced at the very end of the twelfth century by decretals of Innocent III, strengthened by early thirteenth century decretals and finally confirmed in 1215 by the fourth Lateran Council; and once incorporated in canon law the inquisition of the

ecclesiastical courts was elaborated in all its details. A special and drastic application of the processes of the inquisition appeared in the "Holy Inquisition," a court which had its origin in the thirteenth century. It was not, however, this extraordinary tribunal but the inquisitorial system of the ordinary ecclesiastical courts which served as a creative factor in the history of criminal procedure in Europe. By the end of the sixteenth century all the states of the continent, following the example of the ecclesiastical courts, had substituted the inquisitorial for the accusatory system in their courts of criminal justice. England, however, retained the latter as the basis of its criminal procedure.

In the history of the struggle between church and state for the civil jurisdiction of their respective courts the twelfth and thirteenth centuries mark a signal victory for the church. The wide scope of ecclesiastical jurisdiction in that period was an expression of the rise of the church, with the pope as its supreme ruler, to that position of temporal as well as spiritual dominion over the world which Innocent III (1198-1216) and his immediate successors not only claimed in theory but also made effective to a very large extent in the practise of the times. In the pontificate of Gregory IX (1227-41) the jurisdiction of church courts included not only *causae mere spirituales*, chiefly cases in regard to marriage as one of the sacraments, but also *causae ecclesiasticae spiritualibus annexae*, namely, engagements to marry, dower, status, legitimation, patronage, the foundation of benefices, tithes, wills and contracts confirmed by oath. It extended also to *causae miserabilium personarum*, especially persons in poverty, widows, orphans and crusaders; it embraced as well cases in which there had been a refusal of legal relief on the part of lay judges and, finally, cases in which a party had committed a sin, a category which was most sweeping in its nature and scope. In the exercise of this extensive civil jurisdiction the church courts were competent to entertain proceedings brought by clerks against clerks, by laymen against clerks, by clerks against laymen.

Several features of this ecclesiastical system of civil justice, notably the stability of the substantive law as embodied in the texts of the *Corpus juris canonici*, a settled and enlightened civil procedure based on documentation and promptness in the execution of judgments, combined to make the church courts popular with litigants; and throughout the later Middle Ages these courts were in fact formidable rivals of lay

tribunals in all the countries of Europe. The competition of ecclesiastical and lay jurisdictions resulted in certain compromises and adjustments. Some subjects, such as marriage, were in general acknowledged by state authorities as belonging properly to ecclesiastical jurisdiction; while as to other subjects the church was able to enforce its jurisdiction in some countries and not in others. The struggle for civil jurisdiction followed the fortunes of the changing relationship between church and state. As states gradually became stronger they centralized their legal systems, improved the courts and enlarged their civil jurisdiction. From the end of the fifteenth century the growth of temporal justice, at the expense of spiritual justice, was ever more marked: one by one many of the subject matters of the civil jurisdiction of the church were absorbed by the civil courts of temporal powers.

As a system of civil justice the mediaeval canon law embraced several branches, each of which was colored by the religious and moral ideas of the church. The canonical principles in regard to possession exercised a direct influence on secular law, notably in the wide extension of the scope of quasi-possession or the possession of rights as opposed to things and in the development of an effective remedy for the recovery of possession. Originating in the criminal procedure of ecclesiastical courts in an age of much violence and spoliation, the *actio spoliū* of the canon law, based in large measure on the Roman interdict *unde vi*, became a civil possessory remedy; and as such it was received in many secular systems, as for example in England where it served as a model for the assize of *novel disseisin*.

One of the cardinal doctrines of the canonists was that bad faith, whenever occurring, was a sin; and this view lies at the basis of the rules of the canon law in regard to prescription, which were in fact developed as a corollary of the canonical principles in regard to spoliation. In addition to *justus titulus* the canon law required for valid prescription good faith on the part of the possessor not only at the beginning of the period of prescription, as in Roman law, but throughout its entire duration. From the fifteenth century onward the canonical rule as to prescription gradually passed into secular law.

The canon law recognized as binding the formal contract concluded either by oath or by *fides promissa* and also the contract formed *solo consensu*. The basis of the canonical principle,

solus consensus obligat, which conflicted with both Roman and Germanic law, was the theological view that a man who does not keep his promise is guilty of the sin of lying and incurs ecclesiastical penalties. The revolutionary character of their doctrine, and particularly the fact that it was at variance with the Roman maxim *ex nudo pacto actio non oritur*, led the canonists to formulate a further essential requirement in addition to consent. Finding this requirement in the Roman *causa* the canonists held it immaterial that a pact was *nudum a solemnitate*, provided only that it was not *nudum a causa*. Applying this doctrine to both unilateral and bilateral contracts the canonists reached the bold conclusion that all promises supported by *causa* were enforceable. While they held conflicting views as to the nature of *causa* they were all agreed that it involved the necessity of some purpose or result to be attained by the contracting parties, such as a definite legal act; and since the preservation of morality was essential they maintained further that this purpose or object must be reasonable and equitable. From this latter requirement the canonists developed the doctrine of equality in the sphere of contract. This doctrine, which was grounded in their economic notions, they applied not only to the formation and subject matter of contracts but also to their termination. Upon equality they based their prohibition of usury and their ideas of the just wage and the just price; and this same principle of equality led them to hold that if one party did not fulfil his promise the other party was released from his, *non servanti fidem fides non est servanda*.

In the creation of its law of contract the church, starting from the basic idea of the repression of sin, stressed the importance of the conscience of parties and in fact clothed conscience with legal obligation wherever there were present the two essential elements of consent and *causa*. With the development of the informal consensual contract there was the accompanying emphasis upon the importance of the intention of the parties and of their *bona fides*. There arose, moreover, an interpretation of contracts based on considerations of equity and natural justice. All of these features of the canonical law of contract influenced the secular laws of Europe in the later Middle Ages and in modern times. They were adopted, in part at least, by the post-glossators and the civilians of the later mediaeval centuries; they passed at an early time into the secular law of Italy, France

and other countries; and they helped to shape the growth of a cosmopolitan system of mercantile law.

During the later Middle Ages, from the twelfth century onward, the canonical law of marriage displaced the secular laws of Europe. From the beginning the canon law adopted the rule of the classical Roman law, *nudus consensus facit nuptias*; but to this consensual contract there was applied the entirely new conception of the sacramental nature of marriage. Upon this basis of a formless consensual contract the church developed that elaborate and comprehensive law of marriage which dominated the family life of Europe in the later Middle Ages. The canonical law embraced not only rules in regard to the formation of marriage but also those respecting impediments, the capacity of parties, the legal effects of marriage, marital property, divorce and nullity. Still preserved and enforced as the law of the Roman Catholic church, the canon law in regard to marriage has exerted in modern times a powerful influence on other ecclesiastical systems of marriage and on the civil marriage laws in many countries.

The civil procedure of the ecclesiastical courts, which was based on the Roman system, forms one of the most important branches of canon law; and it has exerted a widespread influence on the civil procedure of lay courts in all parts of Europe. While its chief influence in England was felt in the processes of the Court of Chancery it affected also the procedure of the common law courts, notably through the introduction of written pleadings. In many respects the canon law, both substantive and procedural, possessed equity features; for through its foundation upon the ideas of sin and morality it stressed the element of individual conscience, as in its requirement of *bona fides*, and enforced legal processes *in personam*. In the period of the ecclesiastical chancellors some of these equitable features of the canonical system were received into the English system of equity. The Court of Chancery became a tribunal of conscience and developed a procedure *in personam*, based on the ecclesiastical procedure, which is still an integral and characteristic feature of the equitable part of the modern legal system of England and of countries which, like the United States, have derived their law from England.

In the *Corpus juris canonici* and the literature of the canonists based upon it the canon law reached its perfection as the classic expression of the legal ideas of the Roman Catholic church.

The rise of territorial states to the dominance of the modern world has meant, however, a corresponding decline in the position of the church which is reflected in the history of the canon law. Many of the ideas of the mediæval canon law still persist as vital factors in the life of society; but in general these ideas find their present day embodiment in the secular laws of the world. The scope of the canon law itself, now codified in the *Codex juris canonici*, has been gradually curtailed. The canon law has lost much of that secular character which made it in the Middle Ages a common and universal law; but, on the other hand, its spiritual character has been given a new emphasis and significance. Adapting itself to the changing conditions of the world since the Reformation the canon law, now restricted in its application to the purely ecclesiastical sphere, is still the principal factor in the control of the Roman Catholic church as a world wide institution and in the spiritual life of all the members of the church, clergy and laity alike. Within its special province the canon law is therefore one of the leading forces in the social life of the present day world. As a means of stabilizing society in the interests of order and justice it holds a prominent position among the legal systems of the world. Its function is similar to that of the many national systems of law and of that body of international law which has as its chief purpose the preservation of peace and the administration of justice among all the states of the world. By holding firmly to her canon law and giving it a modern and codified form the church has preserved and strengthened one of the most effective agencies for the legal and moral discipline of society.

CÁNOVAS DEL CASTILLO, ANTONIO (1828-97), Spanish statesman and writer. Cánovas was graduated as lawyer from the University of Madrid, but turned to politics rather than law. He held his first ministerial post in 1864. His real prominence, however, began with the exile of the queen, Isabella II, in 1868. He worked actively and openly for the restoration of the house of Bourbon, receiving special powers for that purpose from the queen; and on December 31, 1874, he brought his plans to fruition with the proclamation of Alfonso XII, son of Isabella II, as king. He was president of the ministerial council from that date until 1881 and on several occasions thereafter. While serving in this capacity he was assassinated by the Italian anarchist Angiolillo.

During his lifetime Cánovas exercised greater influence in Spain than any other man in public life. He drafted the constitution that was in force from 1876 to 1923 and included in it his conception of the *principe monarchique*, a conception akin to the French doctrine of Royer-Collard and Guizot. Cánovas was also influenced by the German historical school. He held that the monarchy was identical with the Spanish state and that the monarch was not an instrument of government subject to creation by the national legal consciousness, since his very title to legitimacy was "continuity in tradition." Cánovas succeeded in imposing upon the rival liberal party his conception of the monarch as the direct source of governmental power. He thus achieved peace, but at the expense of the political education of Spain and consequently of its internal, constitutional development.

His authoritarian view of the state made it difficult for him to grasp colonial problems and imparted to his parliamentary proclamations of July 1, 1890, all the intransigence of a death struggle. "Spain," he said, "will spend its last peseta and the blood of its last man to keep Cuba." The liberals tried to correct this policy but failed. Cánovas was a thoroughgoing protectionist, the author of an, important commer-

cial treaty between the United States and Spain, negotiated in July and August of 1890.

Cánovas was generously gifted with literary, philosophical, political and historical talents. His political and social works were collected in *Problemas contemporáneos* (3 vols.); Spanish culture during the first half of the nineteenth century is described in *El solitario y su tiempo* (2 vols.). Of his historical works, the following deserve special mention: *Bosquejo histórico de la casa de Austria en España* (ed. by J. Pérez de Guzmán y Gallo, Madrid 1911) and *Estudios del reinado de Felipe IV* (2 vols.), both of which are devoted to a keen analysis of Spanish decadence in the seventeenth century.

CANTILLON, RICHARD (1680? 1734), author of the *Essai sur la nature du commerce en général*. This single surviving work of a forgotten banker was written probably in French and as early as 1725 but was not published until 1755 when it appeared in the guise of a translation from the English. It was rediscovered and popularized about 1880 by Stanley Jevons, who hailed it as "the cradle of political economy."

The *Essai* is devoted in part to the principles of wealth and in part to those of exchange and foreign trade. Although the treatment of the latter is intelligent it was only the former which had a marked effect upon subsequent economic thought. The physiocrats acknowledged their debt to the *Essai*, several Englishmen, such as Postlethwayt and Harris, drew heavily from it without acknowledgment and Adam Smith recognized its contribution.

Cantillon insists that currency, whether paper or coin, is not the true measure of the wealth of a state and boldly transfers the problem from the field of circulation to that of production. He maintains that the source of all wealth is the land. Returns from the land comprise three kinds of income: the first pays the expense of cultivation; the second pays the profit of the operator; finally the third goes to the owner. Non-agricultural enterprises offer no equivalent to the third kind of income. This was to be the "fundamental truth" of the physiocrats. Follow-

ing Petty he concludes that the intrinsic value of all commodities is determined by a certain amount of land or of labor. While his conclusion is still tentative and indefinite it nevertheless points beyond the physiocrats and already foreshadows the monumental simplification of Adam Smith.

CANTOS Y BENÍTEZ, PEDRO DE (dates of birth and death unknown), Spanish economist and statesman, active at the middle of the eighteenth century. Cantos wrote *Escrutinio de maravedises* (Madrid 1763) to furnish a basis for determining the sums required to pay obligations in terms of money no longer current and to explain the depreciation of vellon or copper money, chronic after 1599. This history of Castilian money, written largely from primary legal sources, though imperfect in many respects is one of the best monographs on Spanish economic history ever produced by a native scholar. Particularly original is his explanation of the depreciation of vellon money. According to this explanation depletion of the public treasury obliged Philip III to coin large quantities of base vellon; Philip IV, embroiled in costly foreign wars, continued and enlarged the issues; since vellon was unacceptable abroad, a premium on silver emerged; depreciation of vellon on the foreign exchange spread to wholesale trade and thence to retail trade, salaries and wages. In an alternative explanation Cantos attributed excessive importance to the decay of the long established institution of public money changers, but he emphasized much less than most contemporaries and predecessors the supposed smuggling of counterfeit vellon into Castile. The prestige Cantos derived from membership in the councils of Castile and of the Inquisition and the frequent citations of rare ordinances in the book have made *Escrutinio de maravedises* a favorite source for subsequent writers on the monetary history of Castile.

EARL J. HAMILTON

Consult: Colmeiro, Manuel, *Biblioteca de economistas españoles* (new ed. Madrid 1886) p. 64.

CAPITAL is a word derived from the adjective form *capitalis* (Latin root *caput*, head), meaning principal, chief. Its various meanings as a substantive are explained as the "several elliptical uses of the adjective" (*Oxford Dictionary*). As first used in commerce capital meant an interest bearing sum of money. The manifold derivative meanings are all of two types, the one implying ownership of a valuable source of income, the other the stock of physical goods constituting the income source. The one idea was from the first characteristically individual, acquisitive and commercial, that of any financial fund having a monetary expression; the other idea was characteristically impersonal and technological, that of the physical goods used to extract, transport, create or alter goods: ships, stores of merchandise, money, tools, machines, houses and, usually but not always, lands.

By a simple association of ideas the original thought of capital as a "fund" for investment was generally connected with lending by the class of passive capitalists, but capital as a "stock" of instruments was connected with borrowing by active enterprisers for the purpose of buying the physical instruments of trade and manufacture. This contrast disappeared, however, when the active enterpriser was pictured as neither borrower nor lender but one who "invests" (clothes) his purchasing fund in the physical equipment in his own possession. Thus the business as a whole might be thought of either as the sum or fund of purchasing power invested, or as the mass of goods which, although not bought with borrowed funds, embodied the owner's business fund.

These two types of capital concepts are so distinctive in essential thought and practical application that confusion inevitably resulted from the use of one word to designate both. This confusion occurred not later than the early years of the seventeenth century, when capital was defined by Cotgrave in 1611 as "wealth, worth; a stock, a man's principall, or chiefe, substance." Here the idea of "worth," implying a valuation, is thoroughly mixed with that of substance, no doubt in the sense of material things in possession. "Capital" thus used is a superfluous and confusing synonym of wealth, goods and stock.

This transition and duplication of terms was confirmed by association of the words capital and stock. The latter, an old Germanic root word, developed in English manifold meanings. The term stock was used in business in the six-

teenth century as "a collective term for the implements and the animals employed in the working of a farm, an industrial establishment, etc."; and at the same time as "a capital sum to trade with or to invest." Even earlier, in the fifteenth century, stock meant "a sum of money set aside to provide for certain expenses; a fund," but this became obsolete.

As English trading companies developed after the fifteenth century, the terms joint stock, capital stock, stock and capital were used with little clear distinction. Adam Smith (*Wealth of Nations*, bk. v, ch. i, pt. iii, art. i) says of the East India Company, chartered in 1600 by Queen Elizabeth: "In the first twelve voyages which they fitted out for India, they appear to have traded as a regulated company, with separate stocks, though only in the general ships of the company. In 1612, they united into a joint-stock." This and other similar examples indicate that at first the "stocks" meant the physical merchandise composing the cargo, and a joint stock company was one in which these stocks were held jointly instead of severally. But Smith refers at once to the "capital" of the joint stock company as so many thousand pounds sterling. His treatment of capital as a whole manifests all the errors that have accompanied the use of this elusive term ever since: the employment of the term as meaning both investment fund and goods bought with it or sometimes "talents" or "skill" acquired by means of it, and as denoting both value and a stock of physical agents, etc. Incidentally Smith suggests a thought that was destined to grow until a certain kind of "circulating" capital, subsistence for laborers, came to be looked upon by J. S. Mill and others as the very essence of the capital concept.

In the three quarters of a century after 1776 the changes in machine production and transportation and in financial and commercial organization were epoch making. Not only did factories owned by individuals and by partnerships increase greatly in size and resources, but great corporations building and operating factories, canals, railroads, steamships, commercial enterprises and banks were chartered and their shares widely distributed to subscribers. At the same time the functions of banks and the agencies for investment of capital funds grew apace. These changes put into the foreground of attention the thought of capital as investment, both active and passive. Whether as cause or as effect this change was accompanied by the ever increasing attention given to commercial profits

as contrasted with national welfare (or rather profit was assumed, in the doctrine of laissez faire, to be identical with welfare). It was during this period too that the word stock was increasingly displaced by "capital." In Ricardo's work (*Principles of Political Economy*, 1817) this transition is perhaps half completed. His "profits" is still from the first word "the profits of stock," and the phrase recurs occasionally, but his training and interests account for his few references to "stock" as physical agents used in technical processes, and for his many references to employers' investment expressed with the pounds sterling symbol. The emphasis is different from that of Smith, but the confusion of two meanings remains.

J. S. Mill, however, (*Principles of Political Economy*, 1848) scarcely uses the word stock after the definition of capital as "this accumulated stock of the produce of labor." But the "function of capital is production," the goods mentioned are all physical and usually their function is described as technological. He is soon, however, hopelessly confused in attempts to distinguish between capital to the individual and capital to the nation. The "capital" employed in production is "worth ten thousand pounds." The chapter on "increase of capital" is mostly concerned with "the produce of past labor" physical objects; but that on "the profits of capital or stock" treats mainly a "rate" of profits on a valued investment. Mill stumbles at length into the notion that all advances "have consisted of nothing but wages," a large portion as direct payment and the rest as "previous advances" which "consist wholly of wages." Nothing could be more explicit—or more erroneous as an explanation of the origin of capital values—ignoring as it does every influence from scarcity of natural materials, from monopoly, from previous profits, from manifold speculative influences and from recapitalization (the revaluation of agents). Mill's capital concept at this point is the fruit of his labor theory of value—herein, however, he has substituted wages for Ricardo's quantity of labor, thereby better concealing the difficulty due to various qualities and values of labor.

The capital concept remained in the circle of English "liberal" price economists as Mill had left it until the late eighties. Among them Marx's conception of capital as an agency of exploitation found no echoes. Yet unquestionably there was here an aspect of truth, one which at that time and since then has been given wide

recognition in Germany. Capital both with Marx and with Mill involved the confusion of acquisition and "production," Marx seeing chiefly the acquisitive and Mill the technical aspect. Classification of capital as one of the three factors of production implies its physical nature and its technological function. Its yield (profit, or interest, as by preference it began to be called) was assumed to be coordinate in nature with rent (of land) and wage (of laborer); yet profits (or interest) as a rate percent of an investment manifestly does not fit into this scheme, and there is a consequent confusion in the theory of incomes.

The psychological school after 1870 made earnest attempts to revise the prevailing capital concept. Jevons, in his incomplete studies of capital (e.g. *The Theory of Political Economy*, 1871, ch. vii; also appendices i-ii in 4th ed. London 1911), offered some original suggestions, but in the end adopted Mill's subsistence (food for laborers) concept. Böhm-Bawerk (*Kapital und Kapitalzins*, 2 vols., 1884-89) as a disciple of Menger sought to make the theory of capital his peculiar domain, but after beginnings which pointed toward a value investment concept and after painstaking studies of earlier views he adopted the conventional confused concept of "capital in general" as "a group of [physical] products which serve as means to the acquisition of goods." This foredoomed him to a productivity theory of interest—the very thing he had attempted to avoid. He also developed a sort of subsistence theory of capital investment in connection with his periods of production in "the roundabout process." J. B. Clark, while engaged in controversy over the single tax, detected the duality of the "orthodox" Mill-Ricardian capital concept and proposed (*Capital and its Earnings*, 1888; also *The Distribution of Wealth*, 1899) to match it with twin terms, "capital-goods" or physical agents including land, and "pure capital" as the (supposedly) permanent fund of value resident in them. Yet in accounting for "the genesis of capital" (physical) and for the capital value Clark too lapsed inconsistently into the old labor theory of value.

Clark's eclectic terminology of "capital goods" and "pure capital," although an unfortunate compromise, has had wide vogue. His reformulation served to stimulate much further discussion, some futile and some fruitful. Partly no doubt this discussion, partly the rapid changes in business organization, notably incorporation, banking, financial investment and

more refined accounting, have caused the trend in recent economic texts toward the more general usage of capital in the valuation, property, investment sense of the terms.

The history of the capital concept helps to explain the early and still persistent confusion of money (a part) with capital (as the whole, of a person's fund of purchasing power) and this, in mercantilist doctrine, with wealth in general. The discussion of the ethical justification of interest (first in the original sense of a premium for a money loan, then in the widened sense of any income from private property) easily became confused because of the ambiguity of "capital." The conservative justified acquisition through capital ownership by pointing to the value of the technological uses of physical wealth; the communist denied to wealth any valuable technological uses, attributing all value to labor and depicting private property as merely a tool of exploitation used by employers to rob the workers of the "surplus value" they had created.

Economic as well as ethical interest theory has suffered from this ambiguity. All use and productivity theories are attempts to explain the rate of premium (or yield) from a financial fund (capital value) by reference to the rent or use-value of a stock of indirect technical agents, without a theory of capitalization to explain first the value of the capital sum or principal.

The terms fixed and circulating capital are distorted expressions of the truth that various kinds and various portions of investments are more or less readily saleable, confused with the technological truth that various physical agents are more or less durable in nature.

The definition of capital determines in turn the meaning more or less vaguely attached to such phrases as capitalistic system, the growth of capitalism and the capitalistic age. Some see in capitalism essentially the use of labor saving machines (perhaps also power driven); this is a technological conception of capitalism. Others, more eclectic, see in capitalism essentially the wage system where the employer owns all the physical agents. But consistently with the value concept capitalism is merely the price system, the commercial exchanging organization of industry, where valuations, incomes and property take on the financial expression.

It is necessary to distinguish certain popular uses of the term capital, notably "nominal capital" of a corporation as the total face value of shares of stock outstanding, taken at par (or sometimes the total authorized); this, however,

can mean only number of shares in the now frequent cases of shares with no par value. Sometimes nominal capital is used to mean the total denomination value of all securities, even bonds, and "capital of a corporation" as denoting these taken at their market value. None of these is properly called "capital" but rather "nominal value [or market value respectively] of corporation shares or securities." Capital as applied to corporations is rather a figure of speech than a consistent scientific term, inasmuch as a corporation (a person only by legal fiction) has revenues and receipts rather than "incomes," and assets (physical or intangible sources of revenues) rather than capital.

While recognizing divergent usage, we may define capital as the market value expression of individual claims to incomes, whether they have their sources in the technical uses of wealth or elsewhere. This is essentially an individual acquisitive, financial, investment, ownership concept. It is a "fund" only in the financial sense, not a stock of wealth. It is the sum, in terms of dollars, of the present worths of various legal claims. It therefore includes the worth of all available and marketable intangibles, such as credits, promises, good will, franchises, patents, etc. as well as the worth of claims to the uses of physical forms of wealth. Their summation as a financial fund is the resultant of a capitalization process. Physical objects of value are not capital, being sufficiently designated as goods, wealth or agents.

Capital as here defined is a conception of individual riches having real meaning only within the price system and in the market place where it originated, and developing with the spread of the financial calculus in business practise.

CAPITAL. LEVY is a form of taxation designed to appropriate to the state not merely a part of the income from capital but a part of the capital itself. It is always conceived of as an emergency measure, applicable to all capitals above exempted minima, and thus differs from inheritance and estate taxes, which, although they may appropriate a share of the capitals affected, are applicable only to the fraction of all wealth descending by death. Estate and inheritance taxes form a part of the ordinary resources of the treasury, while the capital levy is collected once for all and is intended to be set apart for a specific purpose, usually the sinking of the public debt.

The idea of a capital levy as a device for the abolition or reduction of public debt is not new. Archibald Hutcheson suggested it in his tracts of 1714 and 1717 and later in his *Collection of Treatises Relating to the National Debts and Funds* (London 1721). Hume ("Of Public Credit," *Political Discourses*, Edinburgh 1752) rejected it upon grounds of practicability and justice. Ricardo defended the plan in his *Essay on the Funding System* (published in 1820 in the 6th ed. of the *Encyclopaedia Britannica*) and in his parliamentary speeches. It was rejected by J. S. Mill (*Principles of Political Economy*, 1848).

The plan of a capital levy became an object of general discussion after the World War in consequence of the vast increase in public debts. The advocates of the levy may be divided roughly into two groups: those who wished to reduce the debt and thus the interest charges in order that the tax burden might be lightened, and those who wished to free the state from the burden of debt charges in order to allow it to make appropriations for social purposes. The former group, like the early advocates of the capital levy, saw in it a mere capitalization of ordinary taxes. Every capitalist was in effect saddled with the interest on a certain proportion

of the debt. He would be no poorer if he cleared off this proportion once for all by surrendering an equivalent part of his capital. The latter group saw in the capital levy a means of redistributing wealth. Most plans for a capital levy provided a certain exemption and applied the principle of progressive rates. Usually it was proposed to tax the net wealth of individuals but to exempt corporations.

As a rule the discussion turned on questions of practicability rather than on questions of principle. The fundamental problem was one of methods of payment. Advocates of the levy considered that payment could be made in cash, in public debt certificates or even in other securities. Some foresaw creation by the state of a special financial organ with the function of accepting and liquidating securities or even real estate surrendered in payment of the tax. There were others who proposed that the state should administer these investments instead of realizing on them. This proposal was criticized on the ground that it would represent the beginning of socialism.

Opponents of the levy maintained that enormous difficulties would be encountered in the process of payment. Few taxpayers would be able to pay in cash or in public certificates. Most private capitals, it was pointed out, consist of industrial or bank securities. The treasury could not accept them all. Would it publish a list of accepted securities to which it would thus be giving its official seal? And what would it do then with these securities? If it sold them a tremendous disturbance on the exchange would follow. If the treasury kept the securities it received instead of realizing on them a grave question would arise as to the competence of the bureaucracy to administer such important assets. Finally, many taxpayers had only their particular industrial, agricultural or commercial business. Like the capitalists with securities unacceptable to the treasury they would be obliged to borrow to discharge the tax. Their credit would be inferior to government credit and the interest they would have to pay would exceed the amount of taxes from which they would be relieved by the extinguishing of their proportionate share in the public debt. Moreover, important corporations or large capitalists could discharge the tax more easily than the more modest industrialist, agriculturalist or business man. The effect of the levy would thus be to stimulate economic centralization.

In a number of cases attempts were made to

apply the capital levy in practise, but the results were by no means so clear cut as the theoretical conclusions. In Germany the law of December 31, 1919, introduced the *Reichsnotopfer* (emergency sacrifice levy), which was conceived of as an extraordinary tax to amortize the debt and to restore the national finances. All fortunes were taxed; only the sum of 5000 marks for each taxpayer was exempt, a like sum for his wife and for each child after the first. The rate was progressive, 10 percent on a capital of 50,000 marks or under, 12 percent on capital between 50,000 and 100,000 marks. It increased gradually until, above 7,000,000 marks, it finally reached 65 percent. These rates were applied to natural persons. For corporations the rate was uniformly 10 percent. The taxpayers who were unable to pay at once could meet their obligations by annuities equivalent to 5 percent of the amount of the tax, plus 1.5 percent for amortization.

The provisions for postponed payments changed completely the spirit of the law. Instead of a capital levy it turned out to be a supplementary income tax. Fortunes were to be appraised as of December 31, 1919, and the amount of the tax determined on that basis. As a matter of fact, the taxable fortune was almost always less than the real fortune. Industrial plant, for example, was appraised according to its purchase price without considering the depreciation of the mark. As the mark continued to depreciate sharply, assessments, although they were figured in millions, finally represented only a small fraction of the real fortune.

The law of April 8, 1922, introducing the *Vermögenssteuer* (ordinary tax on capital) provided that the *Notopfer* would be levied only up to the amount of 40 percent of the sums due. The rest would be replaced during a certain number of years by special taxes supplementary to the *Vermögenssteuer*, which was to be determined according to fortunes as of December 31, 1922. But in 1923 came the complete collapse of the mark. The evaluation of December 31, 1922, no longer had any significance. The *Vermögenssteuer* was canceled. When it was reorganized in 1925 there was no longer any question of special supplements.

Finally the sums that were collected as a levy on capital were not used to amortize the debt but were simply treated as part of ordinary financial receipts.

A capital levy was instituted in Italy by royal decree of November 24, 1919. All property,

whether owned by citizens or aliens (diplomatic agents excepted), was subject to the tax. In consequence of extension of time granted the taxpayers, however, it lost all the characteristics of a true capital levy and was transformed into a supplementary income tax. As in the case of Germany, the receipts from this extraordinary tax, although intended for debt amortization, were treated as part of the ordinary treasury receipts.

The only country in which the capital levy yielded substantial results was Czechoslovakia. Here the circumstances of its introduction were peculiar. To prevent the influx into Czechoslovakia of notes which the bank of Vienna continued to issue, the Czech government had undertaken to nationalize its currency. To this end all notes circulating in Czech territory had to be presented for stamping at the beginning of 1919. Half of the notes were retained by the authorities, who delivered in exchange 1 percent forced loan certificates. Half of all deposits in the bank of issue and half of the treasury certificates were likewise commandeered and applied to the forced loan. To amortize this loan and to restore its finances the government by a law of April 22, 1920, introduced a levy on capital applying to all fortunes in excess of 50,000 crowns. The rate began with 4.5 percent and increased slowly to a maximum of 50 percent above 100,000,000 crowns. Payment was to be made in ten or twenty-year periods and time extensions could be granted in certain instances. Property was to be assessed as of January 1, 1920. The yield of the tax had been estimated at 10,000,000,000 to 12,000,000,000 crowns, but the actual yield was about 6,000,000,000, approximately 600,000,000 or 700,000,000 gold francs. Payments were largely effected by means of the forced loan certificates, and the receipts served effectively to amortize the public debt.

Whatever may be said in defense of the principle of the capital levy, it must be admitted that the question generally presents itself from the practical angle only when the finances of the state are disorganized and currency is in course of depreciation. Such conditions are extremely unfavorable for carrying out a large levy. On the other hand, when finances are running smoothly, when the budget is balanced and the currency stabilized, everyone or nearly everyone shrinks from such an experiment which threatens to destroy a painfully acquired equilibrium.

CAPITAL PUNISHMENT is the practise of deliberately putting to death an offender as a measure of social policy imposed by the governing authority of the community. It is not safe to generalize about the prehistoric laws and customs from which this practise originated, for like all such laws and customs they are wrapped in obscurity and must have varied most widely in different ages and in different types of communities. If we may judge of them by what we know of the scattered communities of primitives who have in the last half century come under scientific observation we are forced to conclude that within the relatively small group of kinsfolk comprising a primitive community human life was a commodity too precious to be sacrificed for any but compelling reasons. The one reason apparently common to all primitive societies was the necessity of ridding the group of a member who had brought upon it the wrath of a dreaded deity by the gross violation of a tabu, such as killing the totem animal of the tribe or committing incest. Homicide, theft and other secular offenses were not primarily the concern of the community but rather of the injured party or of his immediate family, who might at will take summary vengeance or compound the felony by taking compensation (composition) from the offender or his family. Such composition seems to have been usual.

In the more advanced civilizations represented by the city-states or empires that de-

veloped in the valleys of the Euphrates and the Nile—from the Babylon of Hammurabi in the twenty-first century B.C. to the Israelitish kingdom fifteen hundred years later—we find death the invariable penalty for wilful homicide as well as for a variety of sexual and other religious and quasi-religious offenses, with the rule of exact retribution, such as “an eye for an eye,” governing other types of offenses. Early Roman law, as represented in the Twelve Tables, and the customary law of the Germanic tribes display the general characteristic of ancient law, which is to regard all offenses against individuals, including homicide, as the private concern of the injured. There was no punishment but only compensation in money or goods to be paid to the injured party. As in more primitive societies the only offenses punishable by the state were those against the state, such as treason or the violation of certain religious sanctions, and the state had but one punishment—death.

Capital punishment for homicide and other secular offenses may be said to have come in with the modern state and its growing recognition of the obligation to maintain peace and order within its boundaries. The practise was most unrestrained in the mediæval period, when the states of Europe cooperated with the church in a ruthless warfare of extermination against witchcraft and heresy, and again at a later period, when England, far in excess of other European countries, employed the death penalty on an unprecedented scale in the effort to suppress crime of every description. The European tradition of the seventeenth and eighteenth centuries was not Roman but barbarian, and the early stages of public justice were characterized by excessive barbarity both in the discovery and in the punishment of crime.

The English colonies in America took over English penal law and policy with many modifications and variations. Capital punishment was everywhere accepted, but while Puritan Massachusetts inflicted the death penalty for a dozen offenses Quaker Pennsylvania recognized only two capital crimes, murder and treason. Witchcraft in most of the colonies, as in England and elsewhere in Europe, was punished with death.

In the history of capital punishment since the intellectual renaissance of the eighteenth century there have been two alternating movements: one a trend toward limitation of the use of capital punishment and the adoption of so-called humane methods of execution; the other an ensuing reaction toward a more stringent ap-

plication. This alternation has on the whole synchronized with the general history of liberal and social reform movements without developing any clear and lasting philosophy of the values involved in capital punishment.

The intellectual renaissance inspired a new humanitarian sentiment which, on the side of penology, found its most effective expression in the work of the Italian scholar, Beccaria, whose *Dei delitti e delle pene* (1764) was a reasoned protest against torture and the death penalty and won an immediate success. Catherine of Russia read it and decreed the abolition of capital punishment in that country. The work did much in England and America to stimulate the growing sentiment against the death penalty. Before the end of the century Sir Samuel Romilly and Sir James Mackintosh were moving the House of Commons, against the opposition of the Lords, to reduce the number of criminal offenses, then over two hundred, punishable with death. The French Revolution hastened the process of abolition on the continent but set up a reaction in England which retarded the movement there until 1832, when horse and sheep stealing ceased to be capital offenses. During the following years the list was steadily reduced until by 1861 there remained only wilful and deliberate murder and attempts against the government, offenses which are still punishable with death.

While this amelioration of policy was due primarily to the increase of humanitarian sentiment it was also in part an outgrowth of the contemporaneous secularization of thought, with the elimination of the ideas of sin and retribution and the increasing acceptance of the utilitarian principle laid down by Beccaria and embodied in the French Declaration of the Rights of Man that “the right to punish is limited by the law of necessity.” This principle has become the controlling factor in modern penological theory and practise.

Since the disappearance of witchcraft accusations treason in time of war or revolution and wilful and premeditated murder are, as a general rule, the only two offenses which have been deemed sufficiently menacing to the social order to require or justify the infliction of the death penalty. In a few American communities, isolated from the prevailing tides of public sentiment, other crimes, such as rape, robbery or burglary, are still treated as capital offenses and in Georgia indictments have recently been returned charging attempts to incite rebellion,

with a demand for the infliction of the death penalty as provided by law. Since the middle of the last century there has been a marked though intermittent movement throughout the western world to abolish the death penalty even for murder. This abolition has been achieved in Austria, Norway, Sweden, Finland, Denmark, Holland, Belgium, Portugal, Italy (partly restored in 1926), Latvia, Rumania, Lithuania, Czechoslovakia, Hungary, Russia and most of the cantons of Switzerland. Even more sweeping has been the process in Central and South America, where only six states (four of them under foreign control or influence) retain the death penalty for murder. Of the British colonies only Queensland in Australia has abolished capital punishment. Only twelve of the forty-eight American states have abolished the death penalty for murder, and of these four have revived it in the reaction resulting from the late war. Thirty-two other states have enacted a compromise policy under which the court or jury decides whether the penalty shall be death or imprisonment. In the remaining eight states, as in the federal law, the death penalty is still mandatory. It is perhaps to the influence of Great Britain that we may, in a measure, attribute the slow progress of the abolition movement in the American states. Penal legislative policy in England is still dominated largely by the same classes of well born and well-to-do which resisted the reform of the penal code a century ago. Penal policy in the United States is in much the same degree influenced by the legal profession, with its natural conservatism reinforced by a traditional veneration for English law and procedure. In a large proportion of cases, however, the law is nullified by the jury's refusal to convict or, as was generally the case for long periods in many of the countries which have now abolished the death penalty—and invariably so in Belgium—by the exercise of executive clemency. France of late years has executed less than one third of the condemned criminals subject to the death penalty, and in 1928 Germany did not execute one of the forty sentenced to death.

Methods of inflicting the death penalty have varied widely, from the most casual, such as abandoning the malefactor to the fury of the mob, to the elaborate system of torture which in the seventeenth and eighteenth centuries in England was a frequent concomitant of public execution by hanging. In the classical period of Greece freemen were disposed of by the ad-

ministration of poison, slaves by beating with staves or by stoning. Rome hurled her ordinary malefactors from the Tarpeian Rock or stoned them to death, crucifixion being reserved for slaves or for the lesser breeds without the law. Beheading with a sword or axe became common in middle and western Europe in the Middle Ages, but in England was ultimately limited to malefactors of high degree, all others being hanged. Death by burning, employed in the ancient world only for crimes involving some religious abomination such as incest, was taken over by the western world for putting an end to witches, or sorcerers, heretics and the like. The practise of burning women as witches led, in England at least, to the employment of this method of inflicting the death penalty on women convicted of felony, and up to the middle of the eighteenth century Negro and other slaves convicted of murder, arson or conspiracy to commit one of those crimes were burned to death in New York, New Jersey and other American colonies.

While France and a few other countries retain the guillotine the more general method of execution to-day is hanging, except where in the United States other methods deemed more humane have been substituted. Led by New York in 1888, twenty-one states, including the District of Columbia, now employ electrocution, while one, Nevada, kills with lethal gas and another, Utah, gives the victim the choice of hanging or shooting.

No method thus far tried has sensibly mitigated either the interest or the horror which the infliction of the death penalty excites in the public mind. Although it takes place within prison walls in the presence of only a handful of people it is still, just as it was when performed in the public square, essentially and unavoidably a public spectacle. That it is a demoralizing spectacle cannot be doubted and it may well be believed that the millions who read of it in the public press and who make it a matter of excited discussion are less affected by the lesson it aims to teach than by emotions of sympathy or even of emulation for the tragic victim. There are many unstable, wavering, suggestible personalities in this vast, invisible audience, and it is a matter of record that notorious executions have often been followed by what newspapers call an epidemic of murder. It is not unreasonable to believe that the total abolition of the death penalty would be conducive to a greater respect for human life in the community at large. Such

views are held today by many, probably a large majority, of social workers, criminologists and other students who urge instead a sentence of life imprisonment with some scheme of commutation of sentence in connection with reconstructive psychological and educational treatment. Those who favor the continued use of the death penalty have long since ceased seriously to use any argument but that of a postulated necessity.

Capital punishment maintains its hold as a human institution because of the fear and resentment which murder excites and because of a persistent faith in its necessity either as a deterrent influence or as the only conclusive means of protecting the community against a convicted malefactor. For this faith there is not the slightest evidential support. Again and again in European and American states capital punishment has been abolished without any resulting increase in the homicide rate, and in many cases its revival has not resulted in the slightest diminution. Statistical evidence is uniformly negative. Indeed, a study of murderers and of the conditions under which murder takes place tends to indicate conclusively that of all criminals the murderer is the one least likely to be deterred by contemplation of the legal consequences of his act. Another important consideration is the fact that where conviction will mean death juries hesitate to pass an irrevocable sentence, and thus allow men of probable guilt to go free. As a consequence fear of capital punishment is probably much less of a deterrent than fear of a less extreme but more certain punishment would be.

CAPITALISM

THE CONCEPT OF CAPITALISM. *Introduction.* The concept of capitalism and even more clearly the term itself may be traced primarily to the writings of socialist theoreticians. It has in fact remained one of the key concepts of socialism down to the present time. Nevertheless, it cannot be said that a clear cut definition has ever been attempted. Even Karl Marx, who virtually discovered the phenomenon, defined only certain aspects of capitalism as the occasion required. When the term is used by socialists in any definite sense it has the character of a political byword with a strong ethical tinge.

Despite the fact that capitalism tends to become the sole subject matter of economics, neither the term nor the concept has as yet been universally recognized by representatives of academic economics. The older German economists and to a much greater extent the economists of other countries rejected entirely the concept of capitalism. In many cases the rejection was merely implicit; capitalism was not discussed at all except perhaps in connection with the history of economic doctrines, and when it was mentioned there was no indication that it was of particular importance. The term is not found in Gide, Cauwès, Marshall, Seligman or Cassel, to mention only the best known texts. In other treatises, such as those of Schmoller, Adolf Wagner, Richard Ehrenberg and Philipovich, there is some discussion of capitalism but the concept is subsequently rejected. In the newer economics it is recognized as indispensable or at least useful, but the uncertainty as to its exact meaning is generally expressed by quotation marks about the word. Representatives of this school are little inclined to attempt the constructive development or more accurate analysis of the concept.

The works of Sombart are the first in which the concept of capitalism has been definitively recognized as fundamental to the system of economic thought. Here it is demonstrated that

capitalism designates an economic system significantly characterized by the predominance of "capital," and it is argued that the word "capitalism," which by its very etymology suggests this feature of the economic system, must be retained as the appropriate term for it. The fact that this term has received a negative ethical emphasis in socialist literature should not qualify its use as a completely non-ethical designation for a definite economic system, particularly since there is apparently no better substitute.

Capitalism as a specific economic system cannot be understood without an analysis of the concept of economic system with a view to pointing out the function of this concept in economic science. Economic life is distinguished as a particular sphere of cultural life by the principle of "economy." This principle as a logical concept is removed from the realm of space and time, but "economy" in the sense of economic life is an existential complex with definite spatial and temporal aspects. All culture, and consequently all economy, is historical. As there is in the abstract no religion, no art, no language, no state, but merely a certain religion, a certain art, a certain language, a certain state, so there is no economy in the abstract, but a particularly constituted, historically distinguishable economic life.

The task of all the cultural sciences is to find ways and means by which to grasp cultural phenomena in their historical singularity. A certain field of culture is rendered scientifically mature when science learns to determine its place in history on the basis of its concrete historical manifestations and to distinguish it in its characteristic phases from other concrete manifestations of the same cultural principle. This is achieved by the introduction of a formative conception not derived from empirical observation, which makes possible the construction of systems. Thus linguistics utilizes the conception of inherent language form, the science of religion the conception of dogma, the science of art the conception of style.

Economic science likewise requires a constitutive conception in order to arrange its material in systems. The function of such a conception is to enable us to classify the fundamental characteristics of economic life of a particular time, to distinguish it from the economic organization of other periods and thus to delimit the major economic epochs in history. A conception which will make possible the systematization of economic phenomena must be derived directly

from the notion of "economy," the essentials of which it must comprise, collate and connect—and not merely in their abstract form, not merely as ideas, but in the concrete, as definite historical facts. These requirements are satisfied by the general conception of the economic system. By an economic system is understood a mode of satisfying and making provisions for material wants which can be comprehended as a unit and wherein each constituent element of the economic process displays some given characteristic. These constituent elements are the economic spirit or outlook—the sum total of the purposes, motives and principles which determine men's behavior in economic life—the form of economic life or the objective system of regulations of economic relations, and the technology employed in economic processes. Defined more precisely, an economic system is a unitary mode of providing for material wants, animated by a definite spirit, regulated and organized according to a definite plan and applying a definite technical knowledge.

It will be observed that the economic system is superior to all other systematizing conceptions hitherto employed, because they stressed merely single prominent characteristics and made it possible to distinguish only single aspects of economic life, whereas the conception of the economic system is broad enough to comprehend every aspect. On the other hand, it is definite enough to encompass the historical concreteness of economic life and is thus far superior for the purpose of framing a system to purely formal ideas such as that of national economy (*Volkswirtschaft*). Finally, it is general enough to permit of application to every conceivable economic institution from the most primitive to the most highly developed.

The Spirit of the Capitalist System. The special character of capitalism will be brought out most clearly if we consider separately the characteristic forms which the three constituent elements—spirit, form and technology—assume in the capitalist system.

The spirit or the economic outlook of capitalism is dominated by three ideas: acquisition, competition and rationality.

The purpose of economic activity under capitalism is acquisition, and more specifically acquisition in terms of money. The idea of increasing the sum of money on hand is the exact opposite of the idea of earning a livelihood which dominated all precapitalistic systems, particularly the feudal-handicraft economy. In pre-

capitalistic systems economic as well as all other thought and action was centered about the human being. Man's interests as producer or as consumer determined the conduct of individuals and of the community, the organization of the economic life of society as a whole and the ordinary routine of business life in its concrete manifestations. Goods were produced and traded in order adequately to meet the consumers' needs and to provide an ample livelihood for producers and merchants; the standards for the expectations of both consumers and producers were fixed by long established usage. The category of qualitative use value was the determining principle of valuation. All social and individual norms affecting economic processes were grounded in human, personal values. On the other hand, in systems dominated by the idea of acquisition the aim of all economic activity is not referred back to the living person. An abstraction, the stock of material things, occupies the center of the economic stage; an increase of possessions is basic to all economic activity. The idea of such an economic system is expressed most perfectly in the endeavor to utilize that fund of exchange value which supplies the necessary substratum for production activities (capital).

While acquisition constitutes the purpose of economic activity, the attitudes displayed in the process of acquisition form the content of the idea of competition. These attitudes, which are logically inherent in acquisition, may be described as freedom of acquisition from regulation by norms imposed upon the individual from the outside, the lack of quantitative limits to acquisition, its superiority over all other aims and its ruthlessness.

By reason of its freedom from regulation capitalism rests essentially on the individual's assertion of his natural power. Every economic agent may and should extend his sphere of action as far as the complete exercise of his powers will allow; in case of failure, however, he completely foregoes assistance. Economic activity is closely associated with personal risk, but the economic agent is free to strive for economic success in any way he chooses provided he does not violate the penal code.

There are no absolute limits to acquisition, and the system exercises a psychological compulsion to boundless extension. The fact that capitalistic enterprise has as its purpose a certain mode of utilizing a stock of goods signifies a complete divorce of the aims of capitalistic

economy from the personality of the economic agent. The abstract, impersonal character of the aim indicates its limitlessness. Activity in the capitalistic system is no longer determined by the needs, quantitatively and qualitatively limited, of one person or of a group of persons. Profits, no matter how large, can never reach a level sufficiently high to satisfy the economic agent. The positive drive toward boundless acquisition is grounded in the conditions of management. It is empirically true, though not logically inevitable, that any enlargement of business reacts to its own advantage, at least quantitatively through an extension of its sphere of exploitation and sometimes also qualitatively through a reduction of costs. This provides the stimulus to the continuous expansion of a business, often contrary to the expressed wishes of its owners and managers. In this peculiar orientation of human activity upon an infinitely removed goal lies the reason for the dynamic potency of the capitalistic system, a potency which renders intelligible all its remarkable achievements.

Acquisition therefore becomes unconditional, absolute. Not only does it seize upon all phenomena within the economic realm, but it reaches over into other cultural fields and develops a tendency to proclaim the supremacy of business interests over all other values. Wherever acquisition is absolute the importance of everything else is predicated upon its serviceability to economic interests: a human being is regarded merely as labor power, nature as an instrument of production, life as one grand commercial transaction, heaven and earth as a large business concern in which everything that lives and moves is registered in a gigantic ledger in terms of its money value. Ideals oriented upon the value of the human personality loosen their hold upon man's mind; efforts for the increase of human welfare cease to have value. Perfection of the business mechanism appears as the only goal worth striving for; the means become an end. The vague notion of progress comes to include only such developments as advances in technology, reductions in costs, increase in the briskness of trade, growth of wealth. *Fiat quaestus et pereat mundus.*

Acquisition which is quantitatively and qualitatively absolute degenerates eventually into unscrupulousness and ruthlessness. Business draws practical conclusions from the revolutionary supremacy of its ideals and seeks, without consideration for any conflicting inter-

Encyclopaedia of the Social Sciences

ests, to clear all obstacles to the limitless and unqualified exercise of acquisition. The intensity of the acquisitive drive attains a point at which all moral and temperamental inhibitions disappear and all conflicting drives become inhibited. The business man is "unscrupulous" in his choice of ways and means, because the selection is based exclusively on their serviceability in the achievement of the final goal, on their usefulness as instruments of acquisition.

When the direction of economic affairs is oriented solely upon acquisition it is inevitable that those modes of economic behavior should be adopted which seem most rational, most systematic, best adapted to the purpose in hand. In the old, precapitalistic economic organization, which is essentially traditionalistic and static, there sets in a process of rationalization representing a manifestation of the dynamic principle. Economic rationality is thus the third dominating idea of the capitalist system.

Economic rationality is manifested in several aspects of the capitalistic business management—its predilection for long range planning, for the strict adaptation of means to ends, for exact calculation. The genuinely capitalistic enterprise is managed on the basis of a plan which extends as far as possible into the future, thus leading to the introduction, among other things, of roundabout methods of production. The execution of the plan is accomplished by means which are painstakingly examined with reference to maximum serviceability for the purposes in hand—a vivid contrast to the ill considered employment of means in more traditionalistic economies. Underlying the planning and its execution are the evaluation and registration of all business facts in precise quantitative terms and the coordination of these records as a significant whole. This adherence to exact accounting is only natural in a situation where all economic acts are regulated in accordance with their pecuniary value and where management looks to maximized profits as its ultimate aim.

Rationalization permeates, of course, the entire scope of business and affects its technical as well as its commercial aspects. It introduces into the sphere of production the most "rational" methods and stimulates thereby the development of scientific technology. It creates rational factory management and leads to proper departmentalization and departmental coordination. The rationalization of the procedures of manual labor results in the employment of the individual worker most serviceably with respect

to the ultimate capitalistic aim. On the commercial side rationalization affects the purchase of production equipment and materials, the sale of the ready product at the most suitable time or in the best market, the creation of new outlets whether through clever salesmanship or through the development of new forms of retailing.

Economic rationality penetrates gradually into other cultural spheres, reaching even those which are only remotely connected with economic life. Under its influence all untamed natural growth disappears and, where it proves disturbing, even the aesthetically individual is mercilessly weeded out. The idea of strict adaptation of means to ends, one of the essential ideologic props of capitalism, permeates the totality of culture and leads in the course of time to a purely utilitarian valuation of human beings, objects and events.

While individual action under capitalism is informed by the ideal of highest rationality, the capitalistic system as a whole remains irrational, because the other dominant capitalistic idea, that of acquisition, of the unrestricted assertion by the individual of his power, leaves the regulation of the total economic process to the uncoordinated discretion of individual economic agents. From this coexistence of well nigh perfect rationality and of the greatest irrationality originate the numerous strains and stresses which are peculiarly characteristic of the economic system of capitalism.

The Form of the Capitalist System. The objective, institutional order of capitalism is characteristically free. The dominance of economic individualism has its counterpart in the far reaching independence of the individual economic agents. The restrictions which law and usage impose upon them affect only the most marginal of their activities; essentially restrictions are intended to forestall merely criminal dealings, leaving a wide area of discretion to the individual. "Economic freedom," an aspect of the philosophy of natural rights, assumes, when regarded as an element of the economic order, the form of a system of positive rights conferred upon the individual by law and morals; these positive rights constitute the substance of economic liberalism.

Capitalistic business is typically private, so that economic initiative is lodged with enterprises which are actuated by the quest for private gain. These enterprises, subject to little regulation from the outside, assume the full risk of failure but enjoy also the unrestricted

chance of success. Their activity keeps the economic machinery of society in motion.

The structure of capitalist economy is aristocratic. The number of economic agents is small as compared with the total number of persons participating in economic life, with the result that a large majority is subject to the power of a few economic agents. In a regime of economic freedom the relation between the economic agent and the persons controlled by him takes appropriately the legal form of a free contract. The dominance of a minority is explained by the fact that because of the high standard of technical knowledge and organizational skill required under capitalism people of average abilities and fortunes are incapable of assuming the direction of production and can therefore no longer act as economic agents as they could under the handicraft system.

The capitalist system, based as it is upon highly developed occupational specialization and functional separation, is marked by a high degree of decentralization. The principles underlying the division of labor in capitalist industry differ from those which governed handicraft economy to the extent that the segregation of a certain range of activities into a distinct branch of industry is determined not by the outlook and limitations of a living personality but by purely material factors, the causal sequences of the technological processes. Organic articulation enforced by an active, creative person is superseded under capitalism by purposefully directed mechanistic separation and coordination. The degree of specialization depends ultimately upon the advantages which it may bring to the private economic agents in their pursuit of profits.

Capitalist economy rests upon an exchange basis, the links between its constituent elements being the connections and relations established in the market. All production is intended for the market, is characteristically limited to the production of saleable goods; all products enter into commercial traffic. Similarly all means of production emerge from exchange transactions, are purchased in the market. No less important is the fact that the connection between economic agents and the persons controlled by them is established by contract entered into in the market; labor is thus treated as a species of saleable goods. The relationship between wants and their satisfaction through production is established indirectly through the medium of price, which regulates the quantity and character of output. Since the guiding principle of capitalism is gain,

there is production only if prices yield profit, if they offer to the individual enterprise the prospect of economic success. This system of satisfying wants is therefore flexible, unlike the systems found in economic organizations oriented directly upon the satisfaction of needs. Distribution of the results of production, involving as it does a conflict between various groups, particularly between the two great classes of recipients of surplus value and of wages, is likewise regulated through the mechanism of pricing.

Finally, the organization of production under capitalism is not limited to any single form. Although large scale production predominates, production on a small scale (e.g. domestic system) also has its place in the system.

The Technology of the Capitalist System must satisfy certain conditions. To begin with, capitalist technology must insure a high degree of productivity. It cannot fall below a certain minimum, because capitalist organization of production, involving necessarily the differentiation between the work of organization and management on the one hand and that of technical execution on the other, would then be impossible. For example, as long as every hunter can manage to subsist on the yield of his daily hunt, there is no room for a capitalist organization of hunting under the leadership of an organizer who does no actual hunting himself. Moreover, this productivity must be as high as possible, because, other things being equal, an increase in productivity means a correspondingly greater profit to the capitalist enterprise. The compensation of the wage earners, which is limited to the amount needed for subsistence, can with increased productivity be produced in a shorter time, and a larger proportion of the total working time remains therefore for the production of profits. Again, an advance in technology, particularly in the technique of transportation, involves capitalist expansion whether through an extension of the markets or an intensive accumulation of stock. Capitalist expansion under these conditions is accompanied by an increase in total profits and, in view of the decline in the costs of production, by a rise in the profit rate.

The technology characteristic of the capitalist system must also lend itself most readily to improvement and perfection. For constant technical improvements are an important weapon in the hands of the capitalist entrepreneur, who seeks to eliminate his competitor and to extend

his market by offering goods superior in quality or lower in price. Moreover, such improvements yield a considerable differential profit, since the entrepreneur can realize a profit larger than the average so long as his improvements do not become widely accessible, and thus tend to reduce the socially necessary production costs. It will be observed that the quest for differential profit is an important dynamic factor in capitalist society.

The scientific, mechanistic technology, which is based on the accomplishments of natural science and breaks through the limitations of an organic environment, meets the tests both of productivity and of perfectibility. In addition, the ideas underlying this technology are in precise correspondence with the spirit of the capitalist system. Thus the rationalistic spirit which permeates this technology merely testifies to the fact that the economic principles of capitalistic organization have been applied to its technical processes. The inorganic character of this technology finds its economic counterpart in the divorce of economic life from the personality of the individual, in the impersonality of all economic relationships. The depersonalization of commercial as well as technical management transforms them into satisfactory instrumentalities for the practise of a technology based on the depersonalization of human labor.

The Capitalistic Enterprise. Modern capitalism made its appearance with the development of the capitalistic enterprise. It represents the form through which an independent existence is granted to business as such. By the combination of all simultaneous and successive business transactions into a conceptual whole an independent economic organism is created over and above the individuals who constitute it. This entity appears then as the agent in each of these transactions and leads, as it were, a life of its own, which often exceeds in length that of its human members. This integrated system of relationships treated as an entity in the sciences of law and accounting becomes independent of any particular owner; it sets itself tasks, chooses means for their realization, forces men into its path and carries them off in its wake. It is an intellectual construct which acts as a material monster.

The capitalistic enterprise has its own aims or, more properly, it has a single, very definite goal, profit; for only this particular goal corresponds to its spiritual essence. While it is in a sense sheer tautology to say that profit is its only goal, for conceptually the capitalistic enterprise is

nothing but an instrumentality for the purpose of profit making, it is nevertheless of great significance that in this economic construct the spirit of the capitalist system and the aims of the individual economic agents become merged. Since the aims of these individuals are essentially arbitrary because they are freely determined, it is merely a happy coincidence if the immanent spirit of capitalism, acquisition, appears also as the subjectively experienced motive for individual action in the form of a striving for profit. The motives of capitalistic entrepreneurs are by no means restricted to acquisitive drives; among them we find a motley array—the desire for power, the craving for acclaim, the impulsion to serve the common good, the urge to action. But as all these motives work out in the capitalistic enterprise, they become, by virtue of an inner necessity, subordinate to profit making. For on closer examination it appears that none of the strivings which actuate the entrepreneur has any chance of success unless the capitalistic enterprise itself is successful, unless it yields a surplus above cost. Whatever other desires the entrepreneur may entertain, whatever subjectively conceived purpose his work may serve, he must always, simply because he is a capitalistic entrepreneur, want his enterprise to flourish, and so concentrate his energies upon the making of profit. This transformation of the subjective purposes of the entrepreneur in the capitalistic enterprise objectifies the quest for profit. The fact that the capitalistic enterprise performs this function justifies the inclusion of the spirit of capitalism as a factor in the causal sequences of capitalist actuality. We do not depart from the realm of fact when we relate the spiritual essence of capitalist economy to its actual driving forces, the motives of the capitalistic entrepreneur, by showing that because of the objectification of the striving for profit these appear to be the necessary realization of this spirit. Marx aptly spoke of “the drive of capital for profit.”

In addition to an aim distinct from the purposes of its owners the capitalistic enterprise has a separate intelligence: it is the *locus* of economic rationality which is quite independent of the personality of the owner or of the staff. At first rational business methods, objectively adapted to make the business profitable, are developed only in the course of time as a crystallization of experience; but in the period of full capitalism we observe the characteristic activity of artificial and self-conscious creation of economic

rationality. Rational business methods are steadily and systematically developed and improved by persons who devote all or part of their time to this pursuit, which may itself be directed toward profit making. Thousands upon thousands of people, ranging in occupation from professors of business disciplines to humble bookkeepers, from downtrodden computers to manufacturers of all sorts of office equipment, are engaged in a perpetual quest for ways and means of perfecting economic rationality. As a result of these manifold efforts there exists at present a highly developed and constantly improving system of procedures (supplemented by specifications regarding the physical equipment to be employed therein) designed to insure business efficiency. This system is important primarily because it exists independently of any specific concern and is applicable to any line of business. Such a ready made economic rationality can be bought by the entrepreneur and installed in his concern to regulate it for the future.

Finally, the capitalistic enterprise possesses also the bourgeois virtues of industry, thrift and stability, which the entrepreneur in the early days of capitalism had to cultivate in his own person in order to achieve success. These have now been transferred to the business concern and it is possible for the entrepreneur himself to dispense with them.

The infusion of the capitalist spirit in material objects affects in a number of obvious ways the course of economic activity. In the first place, management becomes more intensive, business planning more definitive. The incorporation of human beings into a material system fixes a definite minimum of energy which must be put forth: just as the speed of the worker is determined by that of the machine, so the tempo of work of the office force, from president to errand boy, is set by an external factor, the routine of the enterprise. The knowledge at the disposal of the executive is also increased thereby; now it far surpasses his personal erudition. Yet he is no longer burdened with the problem of the perfect organization of his business, which formerly consumed a large proportion of his energy; he is relieved of much useless activity and is thereby freed for specifically entrepreneurial work. Secondly, objectification of the capitalist spirit helps also to extend its domain. Thus the spread of the capitalist ideology over the entire world and to all strata of the entrepreneurial class is easily explained by the fact that economic

rationality can be readily transmitted. Finally, the same process contributes to the spreading uniformity of economic life. Since economic procedures are objectively selected for their maximum serviceability in the achievement of certain ends, the fact that the ultimate aim is the same wherever capitalism prevails explains the increase in similarity of these economic procedures along with the development of economic rationality.

THE CAPITALISTIC ENTREPRENEUR. *The Ideal Entrepreneur* combines the traits of inventor, discoverer, conqueror, organizer and merchant. He is an inventor not so much of technical innovations as of new forms of organization for production, transportation and marketing. Moreover, the entrepreneur as inventor does not terminate his activity with the formulation of the invention; in utilizing it he improves and vitalizes it in countless ways. The discoveries of the entrepreneur are in the realm of new outlets for his products, whether these be new territories or new layers of demand in areas already exploited. The entrepreneur is a conqueror in that he overcomes all obstacles and is courageous enough to take great risks for the success of his enterprise.

In his capacity as organizer the entrepreneur unites many individuals in a common and effective endeavor and so manages human beings and inanimate objects that he wrests from them the maximum productivity of which they are capable. To achieve such results the organizer must in the first place be a keen judge of human potentialities; he must be capable of selecting from a great number of people those best adapted to his particular needs. He must also have mastered the art of shifting responsibility, in part, to subordinates and of advancing those who, with the expansion of the enterprise, will take over systematically various phases of his own job. In this connection the gradual crystallization of the less important functions of the executive and their assignment in the course of years to a directorate, as accomplished by Alfred Krupp, must be regarded as a particularly distinguished example of functional separation and delegation. Similar problems are encountered in the organization of factory personnel. After the services of a promising worker are secured, he must be systematically trained and then assigned to a task which will develop his maximum serviceability. The entrepreneur must attend to the proper organization of groups of persons set to work together and, if there are several such

units, he must establish the best possible relations between them. It would be erroneous, however, to consider that business and factory involve merely the clever choice of technically most advantageous nuclei for grouping men and materials. Special geographical, ethnological, commercial and other conditions must be taken into account in making such selections. The organization which is relatively best is practically more important than the absolutely perfect one.

The entrepreneur as merchant is not merely a specialist in the buying and selling of goods, for the term merchant is here employed to designate one who is charged with definite functions in the capitalistic system. There are professional traders who are indeed anything but merchants; and those who go out "in search of wealth" and of whom our historians tell such an edifying tale are in most cases no merchants at all. Trading or merchandising may imply a number of very different things. It may cover such activities as the equipping and arming of ships, the recruiting of warriors, the conquest and pillage of new lands, the loading of the booty on ships and the sale of it at home to the highest bidder at public auction. Or it may mean the purchase of an old suit of clothes after clever spying upon a gentleman in dire need of money who resisted previous offers to sell it, and its sale to a country yokel who is eventually persuaded by the eloquence of the seller. Trading may also mean security speculation. Obviously the specific differentia of the merchant vary from case to case. Thus in the precapitalistic period to trade on a grand scale, as did the "royal merchants" of the Italian and German commercial cities, one had to be above all an adventurer, combining the traits of discoverer and conqueror. Yet to be a merchant in our sense of the term—the functional rather than the occupational sense—is to conduct a lucrative business, to combine the activities of calculation and negotiation. The merchant is a shrewd, speculating calculator and a persuasive negotiator.

As a calculator the merchant must conduct profitable transactions, buy cheap and sell dear, whatever the object of purchase and sale. Thus, assuming a fully developed enterprise, he must purchase the material and personal factors of production at the lowest price; in the process of production proper he must be continually on the lookout for the most economical employment of these factors; later he must sell the finished product, or whatever else he may have

to sell, on the most advantageous terms to the person who can pay most in the best of the seller's markets when demand is greatest. To master these tasks he must be able to "speculate" and to "calculate." To speculate, in this sense, is to draw correct conclusions applying to the individual case from the evaluation of the total market situation. It necessitates a correct economic diagnosis. It implies a survey of all facts bearing upon the market and the recognition of their true interrelations, an accurate estimate of the significance of individual events, a correct interpretation of certain symptoms, a precise anticipation of future possibilities and finally the selection with a sure grasp of the one most advantageous combination out of a hundred possible ones. To do this the merchant must be able to see with a thousand eyes, to hear with a thousand ears, to feel with a thousand antennae. Here he discovers needy gentlemen or warlike states and offers them a loan at the right moment; there he unearths a heretofore unexploited group of laborers who will work for a few cents less. In one case it is a question of gauging the sales possibilities of a new article and in the other of accurately estimating the influence of a political event upon the temper of the stock market. The merchant's ability immediately to translate all his observations into monetary terms, confidently to combine the thousand separate figures into an integral estimate of the chances of profit and loss, reflects his qualities as a "calculator." And if he be master of the art of instantly reducing every phenomenon to a figure in his ledger he is a "wonderfully shrewd calculator."

In order to succeed the merchant must have not only the sure instinct for a lucrative transaction; he must also be able to carry the transaction through by negotiation. The capacities required resemble those of a skilful mediator between two conflicting parties. For negotiation implies the power to persuade one's opponent, by advancing arguments and refuting objections, to accept a certain proposal. Negotiation is a bout with intellectual weapons. The negotiations carried on by a merchant have to do with the sale or purchase of goods, whether these be shares of stock, a business unit or a loan. Bargaining in this sense covers the case of a petty peddler who higgles with the cook over a rabbit skin and that of the old clothes man who spends an hour talking the country huckster into buying a pair of pants. Yet it also applies to Nathan Rothschild, when under particularly

complicated circumstances he closed a million dollar loan with the Prussian negotiators in a conference that lasted several days, to the representatives of the Standard Oil Company when they conferred on a general rate agreement with the railroad companies of an entire country, and to Carnegie and his men when they discussed with J. P. Morgan and his associates the taking over of the Carnegie plants valued at hundreds of millions. The striking differences between these cases are purely quantitative; the core of the matter remains the same whether the interests involved are measured in millions or pennies. The essence of all modern trading is negotiation, which need not always be verbal or carried on in person. It may be silent as in the case of a seller who by resorting to all sorts of advertising devices succeeds in impressing upon the public the merits of his wares. This is truly a modern example of "silent trade."

Ever present is the problem of convincing the buyer or the seller that the bargain will be to his advantage. The ideal of the seller is realized when an entire population comes to consider as vitally important the purchase of the article which he is advertising, when a panic seizes the mass of the people who fear that they have missed their opportunity to buy (as in times of feverish excitement in the stock market). To arouse interest, to gain confidence, to stimulate the impulse to buy—this is the climactic accomplishment of an effective trader. The way in which he achieves such results is immaterial; it is sufficient for our purposes to know that not physical but merely psychic compulsion is used, that the other party enters the agreement of its own resolve and not against its will.

The Entrepreneur in the Period of Full Capitalism. During the period of full capitalism, which covers approximately the period from 1750 to 1914, the position of the entrepreneur was materially changed in several respects. In the first place, several important tendencies affected the character of entrepreneurial activity. One of these was the tendency to dissociate capital ownership from executive management. The movement away from single ownership or partnership to corporate ownership was paralleled in the substitution of the hired executive for the owner entrepreneur.

Another tendency was that toward increasing functional specialization in entrepreneurial activity. This tendency manifested itself above all in the progressive emergence of the entrepreneur *per se*, stripped of all subsidiary functions.

This process, the beginnings of which may be discerned even in the early capitalist era, was now approaching completion. General supervision, improvement of technique, office organization and other duties with which the entrepreneur originally had to concern himself came to be cared for by specialists in his employ. Even the question as to whether a certain business proposition would pay, the calculation of probable costs and profits, was delegated by entrepreneurs to special functionaries, the "efficiency experts." Within this more and more narrowly circumscribed sphere of entrepreneurial activity individuals began to concentrate more intensively in certain fields: the banks developed specialists for contacts with industry, for the flotation of stock issues, for the improvement of deposit banking; industry demanded specialists in plant organization, in purchasing and marketing, in financial management.

At the same time, however, there was also a tendency toward the integration of functions. There appeared a limited number of universal super-entrepreneurs who combined banking and industrial power. The most popular road to such comprehensive activity was simultaneous membership in boards of directors of several corporations.

The spiritual adjustment of the entrepreneur to this change in the character of his activities took the form of a differentiation among entrepreneurs on the basis of mental type, range of interests and effectiveness in varying environments. We may distinguish among them three different types: the expert, the merchant or the business man, and the financier.

The expert centers his interest in his particular product. He is definitely tied down to a single branch of production, as is seen most clearly in the case of the entrepreneur who is also a technical inventor. The inventor-entrepreneur aims to bring about widespread adoption of his invention by producing on as large a scale as possible. Plant organization is his major concern, and his chief objective is to procure and make the best use of the proper working forces. Of the three markets—for capital, for labor and for finished product—the labor market is the one in which he is primarily interested; and of the three possible kinds of competition he prefers the competition in service.

The merchant's starting point is the market demand; he is determined to supply the products which he considers most saleable. Anticipating future demand, which he stimulates with clever

propaganda, the ideal merchant creates wants and proceeds to supply the means for their satisfaction. The commodity market rather than the labor market is the main field of his activity, and his important contribution is not organization of the plant but improvement of the sales mechanism. He uses the power of suggestion as his weapon in the competitive struggle.

The financier's important activity is the creation and accumulation of capital by technical manipulations in the stock market. His appropriate milieu is the capital market and his creative powers are expressed in the promotion of new companies or mergers, holding companies and other financial aggregations. His tendency is towards competition of power.

Logically these three types—expert, merchant and financier—represent successive stages of increasing intangibility, of a progressive loss of concreteness in entrepreneurial activity. In a certain sense they follow also a historical sequence. The expert is more a product of early capitalism than of fully developed capitalism, when the other two types appear more and more frequently. The financier becomes really important only after the process of concentration has overtaken that of economic expansion. It must be understood, however, that these ideal entrepreneurial types are seldom encountered in real life. The actual entrepreneur is often a combination of two of these types, generally of expert and merchant or of merchant and financier. It is equally obvious that the demands made upon the entrepreneur and consequently the opportunities offered to each of these types differ in different branches of business. Industries requiring great mechanical precision in the manufacturing process are fertile soil for the expert; the merchant thrives in industries dominated by mass production; and the financier exploits such opportunities as the promotion of new railways.

Something must be said also of the social and national origins of the entrepreneurial class in the period of full capitalism. This period is characterized by an increasing democratization of its economic leadership: entrepreneurs are drawn from a continually growing number of social groups, and in the course of time lower and lower strata of society are tapped for this purpose.

Statistics for a sample of the English cotton industry before the war (Chapman, S. J., and Marquis, F. J., "The Recruiting of the Employing Classes from the Ranks of the Wage-Earners in the Cotton Industry" in Royal Statistical

Society, *Journal*, vol. lxxv, 1911-12, p. 293-306) offer an apt illustration of the process of democratization. Of 63 manufacturers engaged in the cotton weaving industry, 48 belonged to the "first generation," that is, they were "employers, managers and others . . . , who have themselves risen from the operative classes or from classes earning no more than operatives." In an industrial city of 100,000 inhabitants, 139 employers who owned 93,400 looms replied to questionnaires. Of these 88 were of the first generation; they owned 49 per cent of the looms while the other private employers owned 44 percent of the looms, and corporations accounted for the remaining 7 percent. In the cotton spinning industry dominated by corporations entire boards of directors were questioned; of 45 directors who replied, 33 belonged to the first generation. In addition, among 45 of the mill managers who responded, 38 were of the first generation. In a special investigation dealing with 20 cotton mills in a cotton center it was found that the first generation included 13 percent of the managing directors, 42 percent of the managers (salary range £200-£800) and 67 percent of the assistant managers (salary range £100-£150).

Even many of the great industrial leaders of our day have risen to their high positions from very humble beginnings, as is evidenced in their biographies which are at present in vogue. A number of German business giants came from the middle class of lower social strata and began their careers in subordinate positions. Ballin was an emigration agent; Bosch, the son of a peasant, had an initial capital of 10,000 marks; Dernburg and Helfferich came of families of scholars; Deutsch was the son of a cantor; Fürstenberg's first position was that of a clerk. After his father's fortune was lost Kirdorf began as commercial manager of a small colliery; Isidor and Ludwig Löwe were the children of a grammar school teacher; Emil Rathenau was an engineer in modest circumstances; and Werner Siemens, an artillery lieutenant, founded his plant for the manufacture of telegraphic equipment with a borrowed capital of 6000 talers. Jandorf, Tietz and Wertheim, the founders of the large department stores, began as petty shopkeepers in the provincial cities in eastern Germany. In the United States the number of magnates who have risen from the ranks is perhaps even larger: Carnegie was the son of a poor Scottish weaver, Ford the son of a small farmer and Harriman the son of a minister in a poor Long Island parish.

The reasons for the democratization of the entrepreneurial group are fairly obvious. During the entire period of early capitalism it was necessary either to be wealthy or to affiliate with the possessors of wealth in order to acquire the capital necessary for a start in business. Consequently there must have been many cases in which one man had entrepreneurial ability and no money, and another money but no ability or inclination to engage in business. In the period of full capitalism the man of wealth can easily employ his money as capital without himself being an entrepreneur, and the impecunious man can more easily procure capital by floating stock or borrowing from a credit institution. "Credit institutions are the props of genius," observed the *Bremer Handelszeitung* in 1856; it is primarily the credit system that makes it possible for a man without capital to be active as an entrepreneur.

No less important is the change in the national composition of the entrepreneurial class. While in the period of early capitalism the center of gravity of economic life was found in the Romanic countries, industrial leadership in the period of full capitalism shifted to the nations of Germanic origin. Thus in the year 1910-11 the joint share (in percent) of Germany, Great Britain and the United States in the world's output of the most important raw and semi-manufactured materials was as follows: zinc 65, lead 71, crude oil 71, copper 76, steel 78, pig iron 79, cotton 80, cotton yarn (number of spindles) 75, coal 82 and coke 84.

It is worth noting also that in all countries the Jews have been capturing a growing share in economic leadership. Although the Jews constituted only about 1 percent of the general population in pre-war Germany, 13.3 percent of the directors of industrial enterprises were of Jewish origin. This percentage was as high as 23.1 in the electrical industry, 25 in the metal industries and 31.5 in the leather and rubber industries. 24.4 percent of the members of supervising councils (*Aufsichtsräte*) in industrial corporations were Jews. They played an even more important part in the management of the banks, which were largely controlled by Jews. There was a similar preponderance of Jews in the large scale retail business: most of the department stores, which in Germany are practically all organized on the Tietz system, were established by Jewish merchants. While these data relate to Germany only, what is true of Germany applies to some extent to all capitalistic countries.

The Importance of the Personal Element in the Capitalistic Economy. It would be erroneous to assume, as is done so frequently, that because of the dominance of the impersonal entity, the capitalistic enterprise, the personality of the capitalistic entrepreneur is submerged and reduced to insignificance. It is true that the prime mover in the economic process has now become the automatic, highly efficient contrivance unrestricted spatially or temporally and unhindered by any personal or organic limitations. The individual, even the individual entrepreneur, inevitably becomes a part of it. The earth is studded with countless factories organized on an identical plan and equipped with machines of delicate precision—all this for the purposes of profit making. Chance, individual and national differences are eliminated. Necessity, uniformity and homogeneity dominate in this quantitative universe. Yet it must not be supposed that the importance of the human personality is debased in this mechanized world. On the contrary, the individual, if he happens to be outstanding, wields in the economic life of this period an influence far surpassing that of any other age.

Although the categories of striving and action are a necessary part of any abstract conception of the universe, the concrete fact remains that something positive must be striven for and something tangible must be done. If modern economic rationalism is like the mechanism of a clock, someone must be there to wind it up. If the capitalistic enterprise tends to become an ever larger and more complicated machine, still it does not dispense with the need for a human being to tend it; and the more complicated the machine, the more intelligent he must be. The government and the army have developed along similar lines; there too we find a gigantic mechanized apparatus, and yet a leader is more than ever indispensable. It is true, however, that the distribution of forces has changed; a central power station—the leading executive—has superseded, at least in the large business units, the great number of smaller ones.

The Russians grasped less than any other nation the peculiar character of the capitalistic economy when they banished the capitalistic entrepreneur and thereby brought the entire mechanism to a standstill. The Americans, on the other hand, display the keenest understanding of capitalism. They place a particularly high value upon personality in economic life, considering that in the last analysis it is the individual rather than the business enterprise, family

or capital that is the driving economic force. In the large concerns a few eminent personalities hold undisputed sway. Rumor has it that H. H. Rogers, once the leading brain of the Standard Oil group and president of the Amalgamated Copper Company, remarked that on boards of which he was a member the vote was taken first, and discussion followed only after he had left.

THE PERIODS OF CAPITALISM. An economic epoch is the stretch of time during which an economic system is actually realized in history. While every economic system appears first within the framework of another, there are some periods during which economic processes reveal in a comparatively pure form the features of a single economic system. These are periods of the full development of the system; until they are reached the system is going through its early period, which is also the late period of the disappearing or retreating economic system. Applying to capitalism this division into epochs, we may distinguish the periods of early capitalism, full capitalism (*Hochkapitalismus*) and late capitalism.

In the period of early capitalism, which lasted from the thirteenth to the middle of the eighteenth century, economic agents, the capitalistic entrepreneurs, and their subordinates, the workmen, still bear the earmarks of their feudal or handicraft origin; their economic outlook still exhibits the superficial characteristics of pre-capitalist mentality. The economic principles of capitalism are still struggling for recognition; traditionalism and the mediaeval idea of working merely for a livelihood still predominate. Likewise the external aspects of economic life frequently resemble those of the earlier period: home industry still prevails; the output of factories and manufactories is still slight; the technology employed is not very far from the traditional rule of thumb. Economic life in general has a decidedly personal cast; the individual and his personal concerns frequently form the center of interest, and the relations between individuals are still for the most part on the old personal basis. In commercial transactions buyer and seller confront each other in person and let their personal likes and dislikes affect their business deals; within the enterprise the employer and workmen are often held together by a personal bond ("patriarchal industrial relations").

In the period of full capitalism, which closed with the outbreak of the World War, the principles of profit and economic rationalism attain complete control and fashion all economic rela-

tionships. The scope of economic activity is enlarged (expansion of markets, increase in the size of business units and plants) and scientific, mechanistic technology is widely applied. It is particularly characteristic of this period that relations which originally involved unmediated actions by living persons are now institutionalized; a system of man made organization eliminates spontaneous contact and forces individual action into a framework imposed from the outside. Thus the relation between seller and consumer loses its personal character in a large retail concern where purchases are made almost mechanically with virtually no human contact (system of fixed prices). The standardization of merchandise and the increasing uniformity of the terms of sale on the basis of established usage (as in the dealings in futures) make the wholesale business quite impersonal. The loss of adaptability to individual differences in factory management takes the form of the standard labor contract. Credit relations are no longer based on personal acquaintance between creditor and debtor; credit transactions are regulated by fixed norms and the credit instrument is completely standardized. The use of negotiable securities—endorsed promissory notes and bills, banknotes, evidences of debt guaranteed by mortgage, bonds and stocks—by means of which it is possible at a moment's notice to introduce into the situation new creditors unknown to the original debtor, impersonalizes and objectifies the credit relation.

Most intimately connected with this tendency toward mediatization and mechanization is the intensified commercialization of economic life, the debasement of all economic processes into purely commercial transactions or at any rate the subordination of their other constituent elements to the commercial one. This is vaguely expressed by such a phrase as "the domination of business by Wall Street," in which we can substitute for Wall Street the name of the central speculative-financial market of any country. This is made possible primarily by the depersonalization of credit relations and their crystallization in transferable, marketable, liquid credit instruments.

The period of late capitalism, upon which we are at present entering, can be best characterized by describing the changes which capitalism has been undergoing in the past decade. We observe first of all that industrialism is spreading to every corner of the world; the hard and fast division and the resulting peculiar relations between in-

dustrial and agrarian countries, both of which were characteristic of the period of full capitalism, are being gradually worn away. In industrial countries the strength of the specifically capitalistic elements of economic life is declining; "mixed" public-private undertakings, state and communal public works, cooperative enterprises and other forms of non-capitalistic economic endeavor increase in number, size and importance. The most important changes, however, concern the internal structure of capitalism.

The economic outlook has recently undergone material changes and will continue to change in the future. The capitalistic spirit at its prime was characterized by psychological strains of peculiar intensity born of the contradictions between irrationality and rationality, between the spirit of speculation and that of calculation, between the mentality of the daring entrepreneur and that of the hard working, sedate bourgeois. At present this strain is relaxing. Rationalism is thoroughly permeating the capitalist spirit, and a completely rationalized mentality is no longer a capitalist mentality in its characteristic sense. Certain special aspects of this change are worthy of mention.

All the differentia of a genuinely entrepreneurial spirit—daring decision, intuitive judgment, instinctive grasp of a situation—become less and less important in the conduct of business. The number of determinable factors is constantly increasing, and the entrepreneur is more and more disposed to build his business upon the foundation of systematized knowledge. This may already be observed in the United States, although only beginnings are discernible in Europe. The budgeting of production, of financial needs, the systematic mapping out of sales campaigns—practices which become increasingly common—represent nothing less than the management of a business in accordance with a system of knowable facts. When such practices are perfected and carried to their logical conclusion, the concern in which they are relied upon ceases to be capitalist in spirit and resembles a public undertaking with a thoroughly systematized and externally regulated management. The manager of such an enterprise resembles a minister of finance, who has to act within a framework imposed upon him from the outside.

It is psychologically plausible that with the increase in the size of the business unit the striving for profit grows less intense; witness such symptoms as the fixed dividend rate, the

reinvestment of surplus—in the United States, for example, some concerns provide from 30 to 35 percent of their new capital in this way—the creation of reserves and similar arrangements. Connected with this is the disappearance of the recklessness, daring and aggressiveness of the typical entrepreneur of old. These qualities are paralyzed and fall into disuse with the spread of cartels and trusts and other manifestations of the tendency toward concentration. It is possible that there is a general tendency to gradual decay of the entrepreneurial mentality.

The form of economic life and its objective order are also changing: freedom from external restraint characteristic of the period of full capitalism is superseded in the period of late capitalism by an increase in the number of restrictions until the entire system becomes regulated rather than free. Some of these regulations are self-imposed—the bureaucratization of internal management, the submission to collective decisions of trade associations, exchange boards, cartels and similar organizations. Others are prescribed by the state—factory legislation, social insurance, price regulation. Still others are enforced by the workers—works councils, trade agreements. The relation between employer and employee becomes public and official. The status of the wage worker becomes more like that of a government employee: his activity is regulated by norms of a quasi-public character, the manner of his work approaches that of a civil servant (no overtime), his wage is determined by extra-economic, non-commercial factors. The sliding wage scale of earlier times is replaced by its antithesis, the living wage, expressing the same principle as that underlying the salary scale of civil servants; in case of unemployment the worker's pay continues, and in illness or old age he is pensioned like a government employee. At present this situation is more characteristic of a country of older culture like Germany, but it is bound to become established also in the United States.

The economic process as a whole has changed also. What used to be a matter of spontaneous, natural development is fast becoming a system of external regulations. By and large, flexibility is being replaced by rigidity. Thus regulation of economic life through the market mechanism, a system under which the links of the causal sequence were demand and supply, market conditions, prices of goods, wages, profits, is gradually disappearing. It is being superseded by the price regulation of combinations or even

of the government; by wage regulation of the trade unions, who pay little attention to the market conditions; by indirect regulation of the geographic distribution of industry through the intervention of the central and local governments, who disregard the natural rationality implicit in the existing situation.

The cyclical oscillations of the economic system, the rhythm of prosperity and depression characteristic of full capitalism, also become attenuated. A large number of considerations bear upon this change. There is an increasing insight into market conditions and the factors determining them. The currency and credit system has been rationalized, better adapted to serve the needs of the existing order. Conditions of production were affected by important changes in the supply of factors of production; thus, while the economic cycles of the past eighty years were conditioned by railroad building and the introduction of electricity, at present the supply of important equipment has reached the saturation point; business has assumed the corporate form of organization, and there has taken place a concentration of economic power; the reserve army of the unemployed has been reduced by a general decrease in excess population. There is more external regulation of business by government (regulation of the promotion of new enterprises, labor legislation) and by labor organizations. The entrepreneurial group has been consciously striving for stability as in the cartels and trade associations. Public authorities have intervened to offset the business fluctuations by withholding orders in periods of prosperity and granting them more generously in periods of depression; this policy will play an increasingly important role. "Stabilization of business" seems to be both the slogan and the accomplishment of this period.

CAPITALIZATION may designate either the process of capitalizing a flow of money income or the par value aggregate of shares of capital stock and of certificates of long term indebtedness issued to those who contribute money or other forms of wealth to a corporation for use as its capital fund. Capitalizing the flow of income is one way of determining the capital value of the income yielding object. The problems arising in this connection are an integral part of the general questions as to the nature of capital (*q.v.*) and interest (*q.v.*) and the psychological bases of market valuation (see VALUATION). The capitalization of an enterprise involves on the other hand problems in financial management.

One of these problems concerns the relation of capitalization to the actual cost of assets and to present and prospective net income. Were the assumptions of orthodox economic theory fulfilled and the cost of productive assets equal to the capitalized value of their income yield, no important practical issue would center about this question. In that case it would not be

difficult to make the par value of outstanding securities equal to the actual cost of the properties of the concern. However, since perfect competition and free mobility of resources are rarely found in economic practise, the nice balance between capitalization and cost, and capitalization and capitalized income yield is seldom realized. The discrepancies give rise to problems of overcapitalization and undercapitalization, of which only the former, for obvious reasons, is likely to be of frequent occurrence and practical interest.

Since the rates which they are authorized to collect include a return upon their capitalization, the charge of overcapitalization has been leveled principally against public service corporations. During the promotion period these enterprises were capitalized without regard to the monetary cost of the fixed plant. It is a matter of common knowledge that the construction cost was often met by bonds, with shares of stock issued as a bonus to those who purchased bonds. It was also customary to have franchises, patent rights, water rights and promotional activities appraised by the promoters and financiers themselves and paid for through bond and stock issues. Overcapitalization would also arise from the faultiness of financial management. In order to pay some return upon outstanding securities, particularly upon the bonus stock, maintenance was neglected and little or no provision was made for property renewals. When the need for making renewals suddenly became urgent, due to the rapid growth of the territory or deferred maintenance, funds for these purposes had to be secured by more security issues. Again, owing to the rapid development of the arts, old plants were obsolescent before their cost could be written off as an operating expense. Additional securities were then issued in order to procure funds for rehabilitation and modernization.

Industrial combinations also have been frequently charged with overcapitalization. The costs entailed in clearing up cut-throat competition and in scrapping much old and duplicated property, on the one hand, and the over-sanguine estimates of net earnings to be realized as a result of the consolidation, on the other, made overcapitalization not only necessary but possible. The desire of a small group to retain the voting control with little or no investment of cash funds was usually an added incentive to excessive security issues. Even subsequent receiverships did not result in a scaling down

of capitalization, for these enterprises usually emerged with a greater load of security issues, even though their character might have changed from interest bearing obligations to equity capital.

Another problem in connection with capitalization is that of the safest and most economical capital structure; that is, of the proper ratio between the various types of notes, bonds and stocks. Generally speaking, the divisions and subdivisions in the capital structure of a corporation, or its financial plan, reflect from a legal point of view the differentiation between creditors' and owners' interests, and from an economic point of view the variation in the degree of risk assumed. Usually the financial plan is based on the theory that capital can be best and most cheaply secured by including bonds, preferred stock and common stock in a ratio which is proportioned to income. Here are applied the well known axioms of finance set up by A. S. Dewing that "(1) bonds should be issued only when the future earnings of the corporations are liberal and reasonably constant; (2) preferred stock may be issued when the earnings are irregular but, when averaged over a period of years, give a fair margin over the preferred stock dividend requirements; (3) common stock and only common stock should be issued when the earnings of the new corporation are uncertain and unpredictable" (p. 296). Investigations seem to indicate that judged by investment market sentiment bonds should be so limited in a good capital structure that their interest charges will equal about one half of the earnings available after taxes and depreciation, while preferred stock dividends should not absorb more than one half of this remainder.

The correct capitalization of a corporation, as to both size and structure, is of preeminent concern to all parties who as investors, creditors or customers may be doing business with the corporation in question. Public regulation of capitalization is therefore frequently undertaken. The extent to which it is carried as well as its emphasis varies from country to country and from industry to industry within the same country. Thus the valuation of properties paid for by stock issues is made subject to verification by semi-judicial bodies in Italy and Germany, in France to approval by the first two meetings of stockholders who have paid for their shares in money, in England to an examination by interested parties of the detailed records. In the

United States boards of directors, from which promoters and bankers are not excluded, are allowed to determine whether securities exchanged for properties and services were issued for adequate and valuable consideration. Similarly the emphasis varies from the protection of stockholders, as opposed to organizers and promoters, and creditors, in countries where general corporation laws are stringent and in those parts of the United States where blue sky laws (*q.v.*) are effectively enforced, to the protection of customers, as in the case of public utilities, banks, insurance companies and similar organizations. In the United States the multiplicity of charter granting authorities and the competition among them for the revenue to be derived from incorporation fees are responsible for the laxity of general public supervision over the organization and operation of corporations. We find, however, public regulation of considerable scope in reference to special classes of corporations.

The most common and best developed type of security control in the United States relates to the issues of public utility corporations. It is intended primarily to prevent overcapitalization through the watering of stock and the diversion of funds for unauthorized purposes, and is thus a means of providing for a sound rate base and of facilitating the task of rate regulation. The system has been introduced in some form in twenty-seven states, the District of Columbia and in the regulation of interstate utilities by the federal authorities. The usual method is to forbid the issue of securities without the approval of an administrative commission. The law usually applies to all classes of public utilities and names the specific purposes for which securities may be authorized. These purposes generally include the compensation for organization and construction costs, the refunding of legal funded obligations and the correction of cases of undercapitalization, *i.e.* the increase in the aggregate par value of securities to a parity with the value of fixed properties as determined by a commission. Except in Massachusetts security laws do not undertake to fix the price at which the securities may be sold, but they do fix the minimum price at which they may be issued, which in the case of stock is usually the par value and in the case of bonds is 75 percent of their face value. The law also provides that bonds shall be reasonably proportioned to stocks, thus leaving the determination of the relative quantities to the com-

mission after an investigation of the facts in each case. This provision is designed to prevent undue burdening of the properties with bond issues and to insure that control and management shall be based upon a substantial financial interest in the property. With the growing tendency to treat preferred stockholders as creditors and to subdivide even common stock into groups with unequal voting privileges, it must be recognized that this intent of the legislators is defeated, particularly where their laws fail to distinguish between preferred and common stock.

Massachusetts was the first state to provide for public regulation of capitalization and it is here that this regulation has been carried farthest. Since early public utility and industrial enterprises in that state were financed largely by means of stock issues, its policy centered upon controlling the issue price of capital stock, with the aim of making the par value of securities equal approximately the invested capital. Legislation was early enacted to prevent the issue of bonus stock and to insure the issue of shares at not less than par. After 1871 the Massachusetts law provided for the selling of stock at public auction. This violated traditional rights of stockholders to preference in subscribing for new issues and opened the way to contests for control between rival interests. In 1894 it was therefore provided that share capital be issued at a market price (*par plus premium*) as ascertained by regulating commissions. At the same time the bonded debt was limited to a figure not in excess of the par value of the share capital. Subsequent legislation was of a more liberal character. The limitation of bonds to an amount equal with stocks resulted in the practise of incurring large floating indebtedness, and a later amendment fixed therefore the ratio of bonds to stock at two to one. Stock issues to cover promotion expenses and working capital were prohibited. In 1908 a very significant amendment was added permitting the issue of shares at a premium but not at less than par, with the issue price determined by the stockholders subject to approval of the commission. The strongest factor in bringing about this change was that the prices of issue had been set so high under the old statutes as to discourage investment. The old premium law was workable only so long as the market price of stocks was rising or the credit market was firm, but with the increasing prevalence of tighter credit conditions the companies found it difficult

Capitalization — Capitalization and Amortization of Taxes 211

to sell their stocks at the price fixed by the commission. Again, utilities were gradually permitted to issue greater proportions of bonds and preferred stocks, and in 1914 street railways were for the first time allowed to incur indebtedness for other purposes than permanent additions to capital. In 1922 permission was given street railways to issue capital stock at a discount, and the department of public utilities was to decide whether such discount should be amortized.

The significance of the functions performed by security regulating commissions may be best summarized in the words of W. Z. Ripley: "Regulative commissions stand between two fires. On the one hand, they cannot lawfully adopt so strict and narrow a policy as to throttle enterprise. On the other, they must not be so liberal as merely to 'rubber stamp' promoters' schemes" (*Railroads: Finance and Organization*, p. 295). In approving the issue of new securities for extensions they have tried to hold the issues down to an amount commensurate with cost. Where past policies and obligations of the companies have been involved in new issues they have exercised a wise discretion in preserving continuity of service and credit; they have adopted financial expedients in each particular case to lead the company out of its financial wilderness.

CAPITALIZATION AND AMORTIZATION OF TAXES. The term capitalization of taxes is properly applied to the case of an object which, being totally or partially exempted from a given general tax, rises in value by a sum equivalent to a capitalization at the current rate of interest of the amount of tax saved. The inverse case, that of an object hit by a special tax

and as a result reduced in value by the capital value of the tax, may best be described as one of tax amortization. In the first case a buyer would pay for the object its original value plus the capitalized tax saving; in the second case he would pay the original value less the capital value of the tax. Thus if a special land tax reduces the net yield of a farm from \$5000 to \$4500, the capital value shrinks from \$100,000 to \$90,000. One who purchases at the latter figure continues to pay over to the state \$500, but this is in effect merely interest on the \$10,000 saved on the purchase price. The abolition by the state of the \$500 annual charge would be equivalent to the free gift of an annuity of this amount or of its capital value, since the farm's value would again rise to \$100,000.

The first conscious experiment in tax capitalization was made in 1788 by the Grand Duke Pietro Leopoldo of Tuscany. Landowners were required to pay into the treasury a sum equivalent to the capital value of the tax based on an interest rate of 3.5 percent. The amount of tax thus redeemed, in terms of capital value, was 8,250,000 scudi out of a possible total of 12,500,000. In 1790, however, the new grand duke, Ferdinand II, yielding to the clamor of the interested parties, canceled the edicts of his predecessor and ordered that the sums paid be refunded and the land tax restored. More successful and better known is Pitt's Redemption Act of 1798 in England, which provided that the land tax, already fixed in 1775 at four shillings per pound, be made perpetual at that rate and that taxpayers be permitted to redeem it at the rate of twenty times the amount of the annual charge.

Amortization theory, as applied to the land tax, plays an essential part in the single tax doctrine of Henry George. Once the whole net income from land had been absorbed by taxation the capital value would have disappeared, and any purchaser would have paid only for improvements. Although the purchaser continued to pay the net rental value as a tax the burden would in effect have been thrown back on the one who owned the land when the tax was first imposed.

In 1814 it was pointed out by Craig that the amortization process was not peculiar to the land tax but extended to all "exclusive" taxes; Rau observed that sometimes the fall in capital value consequent on special taxation was obscured by a change in the rate of interest or other factors; and Schäffle stressed the general character of the

theory. The classic theory received its most definite formulation at the hands of Seligman, who summarizes as follows the conditions under which amortization may take place: taxation must be unequal, since if there is no excess of a given tax over the general taxation level there is nothing to be capitalized; the object taxed must have a capital value which is susceptible of diminution; the object taxed must be relatively durable in character; the tax must not be capable of being shifted.

Of all these conditions the one which demands the most careful analysis is the first. To be amortized a tax must rest on the taxpayers with unequal weight; but this raises the question, what is equality in taxation? Clearly a flat rate general tax on all income from capital alone is not an equal tax, because it exempts labor incomes. It might lead to the investment of new savings in education, etc., and subtract them from ordinary investments. Thus it might raise the rate of interest and to this extent might reduce capital values. This would mean that such a tax is in some measure amortizable. Are we to regard as equal a general tax on all incomes (capital as well as labor), which in almost all countries is progressive, with exemptions at the bottom, and which frequently differentiates against property incomes? It is obvious that equality of taxation is a very refined and complex idea, which allows for apparent inequalities, intended to equalize the psychological burden of taxation for different taxpayers. An equal tax may be a compound of very unequal separate taxes whose total impact on the several taxpayers is evenly distributed. As this ideal of equal taxation is very difficult of attainment there will always be a residuum of inequality to which the amortization process can be applied.

In the classic theory amortization depends on the circumstance that a special or differential tax does not reduce the general rate of interest in proportion to the rate of taxation. If the rate of interest is 5 percent a 10 percent tax on a particular form of income does not change the rate of interest, because new savings can be invested in non-taxed fields. If the tax is general and all fields are equally hit, taxpayers can nowhere find investments free of the tax. All investments will yield a lower net return on account of the tax, but since they all suffer alike the rate of interest will be uniformly reduced from 5 to 4½ percent, capital values remaining therefore unchanged. In other words no amortization can take place.

It is tacitly assumed, in the classic theory of amortization, that whatever is taken from the taxpayer by either special or general taxation is lost to him completely. If \$500 is taken from a \$5000 income by a tax it is assumed that the situation of the taxpayer is the same as it would be if his income were diminished an equal amount by natural causes. This assumption has been challenged by Einaudi in a paper published in 1912 and republished in enlarged form in 1919. Einaudi points out that we cannot appraise the effects of an equal tax apart from the effects of the use of the proceeds of the tax. A 10 percent general tax, as such, reduces all incomes; but without the tax and its use to the furtherance of the state ends economic society could not exist and private incomes would not be forthcoming. An equal tax is not to be regarded merely as a subtraction from private income, but as the portion of the total social income which ought to go to the state if that total income is to reach a maximum. Optimum taxation may be a composite of equal or general taxes, with special or differential taxes on windfall incomes and others which may be deemed worthy of a special burden. The ultimate effect of the introduction of an optimum tax system would in theory be an increase in the total social income and in the flow of new savings, a fall in the rate of interest and a rise in most individual incomes and their capital values. In cases of differential taxation there would be a decrease in the relative amount of the incomes affected. If the effect of this decrease were not counterbalanced by the fall in the rate of interest and the general increase in total social income, the capital value of such specially affected incomes would decline, or in other words the principle of amortization would become operative.

Actual tax systems are far from optimum either as to their structure or as to the use of their yield. Assuming small additions to the existing tax structure, to the extent that such new taxes depart from the optimum they do not increase and may even reduce total social income. The effect on the rate of interest will probably be to raise it above the level which would have obtained without the additional increment of taxation. Most individual incomes would decrease and their capital values would fall. The fall would be particularly marked in the case of incomes subject to special taxation or disproportionately burdened by the general system. Incomes less than proportionately burdened might rise and their capital value increase.

Capitalization and Amortization of Taxes — Capitulations 213

In the actual world the phenomena of capitalization and amortization of taxes rarely, if ever, present themselves in clear outline. Any extensive fiscal change, whether involving mere quantitative increase or a shift in the objects of taxation, is likely to involve both types of phenomena in more or less disguised form.

CAPITATION TAXES. See POLL TAX.

CAPITULATIONS. This term is used to indicate the regime of extraterritorial privileges or immunities of jurisdiction enjoyed by foreigners in the Ottoman Empire. The early grants of privileges by Turkey were made voluntarily, as for example when Mohammed the Conqueror captured Constantinople and confirmed the ancient privileges of the Genoese living in Galata. These privileges were not in derogation of the rights of territorial sovereignty but were granted rather in the free exercise of sovereignty and were revocable at the sultan's will.

The origin of these privileges is to be found in the view held until comparatively recent times that law was personal, following a subject wherever he went. It was on the basis of this view that the Byzantine emperors permitted subjects of some of the western mercantile city-states residing in imperial territory to be ruled by their own courts, presided over by consuls. In England

and Holland well through the Middle Ages such functions were exercised by consuls. In a case where the local law was grounded in religious principles and social usages profoundly alien to Christians and, in fact, reserved to Moslems, it was logical and preferable to leave the former free to settle their disputes according to their own laws and to regulate their affairs through their own magistrates. The Capitulations originally intended little more.

In 1454 Mohammed the Conqueror signed with Venice a treaty of a reciprocal nature granting extensive extraterritorial rights, thus making the Capitulations a matter of international rather than of municipal law. In 1528 Sultan Soliman formally confirmed the privileges long enjoyed by French and Catalan merchants in Alexandria. Soliman treaty engagements whereby any concessions made to one foreign power should accrue to all were entered into by Francis I and Soliman in 1535. They mark the real commencement of the regime of the Capitulations, and became the model for future treaties of similar import, *inter alia* those with England, Holland, Austria, Russia, Germany and the United States (1830). The essential features of the Capitulations were that in lawsuits involving foreigners the foreign consul had jurisdiction; and in suits between foreigners and natives what was in effect a mixed tribunal had jurisdiction. Further privileges were exacted by force and others boldly assumed by the powers without effective resistance on the part of Turkey.

The Treaty of Adrianople of 1454 between Turkey and Venice specified a duty of 2 percent on goods sold by Venetian merchants in Turkish ports. The inclusion of this provision in subsequent treaties with other powers resulted in the unforeseen and humiliating claim that Turkey might not alter its customs tariff without the consent of all nations having capitulatory rights. Inasmuch as this consent could be obtained, as a rule, only by other concessions as a *quid pro quo* it resulted in considerable foreign control of the treasury. In the course of their later development the Capitulations made possible a status of practical immunity of foreigners from all local jurisdiction and thus constituted a flagrant encroachment upon the sovereignty of Turkey. Foreign banks and commercial houses entirely exempt from Turkish supervision were founded and operated to the disadvantage of native institutions. Foreigners were exempt also from personal taxes and imposts. Turkish employees of foreign corporations came to enjoy a quasi-

immunity from local jurisdiction, and this created a considerable class of protégés who often occasioned serious diplomatic disputes and intrigues. Foreigners misused their immunities to the extent of practising with impunity smuggling, bribery and corruption. The right of inviolability of correspondence led to the establishment by six great powers of foreign post offices which were utilized by Turkish subjects as well as by foreigners. The extraordinary privileges of missionary institutions resulted in certain instances in their becoming centers of political propaganda and diplomatic intrigue. The Capitulations had one positive effect. They served to introduce western principles of justice into the Near East and to provide materials later used by the Turks in reforming their judicial system.

By the time the evils of the Capitulations were recognized they had become so well grounded in international law and tradition that their abrogation was almost impossible. As early as 1856, when Turkey assumed full status as one of the European concert of nations, she raised the question of abrogation, but not until the World War was she in a position to terminate this humiliating regime on the general grounds of the right of sovereign independence and in conformity with the *rebus sic stantibus* rule of interpretation of treaties. On September 10, 1914, the Turkish government served notice that the Capitulations would be abrogated on October 1. The United States and other powers denied the right of Turkey to abrogate solemn treaty rights by unilateral action. The failure of the Senate to ratify the Treaty of Lausanne of 1923, which provided for the abolition of the Capitulations, left the United States in the unique situation of having to fall back upon the rights granted by the treaty of 1830. Realizing the futility of insisting on its legal pretensions to extraterritorial privileges, the United States entered into a *modus vivendi* whereby it enjoys the same rights as other powers. It is important to note that the secularization of the Moslem legal system which began under the Young Turks has presumably advanced under the Kemalist regime sufficiently to constitute a valid theoretical ground for the abrogations of Capitulations, since religious distinctions are no longer to be drawn by the Turkish state.

Although Egypt long since ceased to be an integral portion of the Ottoman Empire and was formally proclaimed a British protectorate in 1914, it continued to maintain the Capitulations,

with some important modifications. In 1875, after prolonged negotiations with those powers enjoying extraterritorial privileges, the Egyptian government put into effect the *Règlement d'Organisation Judiciaire* instituting the remarkable system of Mixed Courts having jurisdiction in all civil and commercial litigation between foreigners and natives, as well as between foreigners of different nationalities. A Court of Appeals, sitting at Alexandria and composed of ten foreign judges and six Egyptian, and District or Trial Courts, sitting at Cairo, Alexandria and Mansourah, composed of three judges, two foreign and one Egyptian, were created. In all there are sixty-five judges appointed by the Egyptian government with the *agrément* of the foreign powers concerned. The United States has two judges in the Trial Courts. The Consular Courts continue to function in matters affecting their own nationals, with the exception of police offenses of a minor sort, while foreigners still enjoy freedom from personal taxation, inviolability of domicile and protection from arbitrary arrest.

A further modification of the Capitulations was made in 1889, when authority was conferred on the Court of Appeals to approve police regulations proposed by the Egyptian government, thus placing offenses of this nature under the jurisdiction of the Trial Courts. A still more important modification, made with the consent of the powers concerned, was the creation in 1911 of a Special Legislative Assembly in the Mixed Courts with power to approve changes and additions to all legislation intended to be applied to foreigners, with the exception of the imposition of new taxes. This system of Mixed Courts has worked with extraordinary success to the satisfaction of Egyptians and foreigners alike.

Other regions formerly parts of the Ottoman Empire abrogated the Capitulations as soon as possible after they had obtained their independence. Greece was granted capitulatory rights in Turkey in 1855. In one remnant of the old Ottoman Empire, Morocco, the Capitulations are still enjoyed by Great Britain (Spanish and French zones), Italy (Tangier zone), Japan, Holland and Switzerland (Spanish zone) and the United States (all zones).

CAPODISTRIAS, JOANNES, COUNT (Giovanni Antonio Capo d'Istria) (1776-1831), Russian and Greek statesman. He was born at Corfu and began his career in the service of the Septinsular Republic (Ionian Islands). His Hellenic patriotism was awakened through contact with certain Greek chiefs and he joined the secret society known as the Hetairia Philike. But he believed that the best hope for the Greek cause lay in Russia, and in 1809 he entered the Russian diplomatic service and gained the confidence of the emperor, Alexander I.

Like many other educated Greeks he had imbibed the doctrines of the French Revolution, or had at least learned its catchwords; and as adjunct minister for foreign affairs he became the inspirer, or at times perhaps only the mouthpiece, of the czar's liberal policies, as Nesselrode was of his conservative reactions. Metternich, indeed, regarded him as chiefly responsible for Alexander's "Jacobinism." This was an exaggeration; but there was something in the added accusation that he was "using Russian policy for Greek ends," and it seems clear that he encouraged Alexander Ypsilanti in his wild adventure into the Danubian principalities.

In 1827 he was elected president of the Greek Republic and was acclaimed not only as the

representative of the national will of the Greeks but also as the symbol of the guaranteed support of Europe. He soon found, however, that liberal principles had no practical application in that turbulent society, and proceeded to apply the Russian methods which he had once employed with great success in the government of Bessarabia; and when the inevitable insurrection broke out he suppressed it with Russian aid. A personal affront to Petrobey, chief of the wild clan of the Mavromichales, led to his assassination.

CAPPONI, GINO ALESSANDRO (1792-1876), Italian educationist, historian and man of letters. Capponi came of an illustrious patrician family of Florence and by virtue of his position, his learning, his literary activity and his part in important civic and cultural movements was over a period of about fifty years the most conspicuous figure in Tuscany. His name is associated with such widely different projects as the founding of the great Tuscan reviews the *Antologia italiana*, the *Guido dell' educatore*, the *Archivio storico italiano*, and the establishment of the first savings bank of Florence. While it was primarily as an intellectual figure that he entered into the Risorgimento, he was a zealous advocate of Italian unification. His conception was a federation headed by the pope, but he was sympathetic toward more extreme views. After 1860 he sat in the senate of the new kingdom of Italy.

Capponi's best works, those which most clearly illustrate his extraordinary insight into social and historical problems, were published either as brief essays or in fragmentary form. It is in such studies as *Sulle dominazioni dei longobardi in Italia* (first published as a series of letters in the *Archivio*) and in the unfinished *Istoria di Pietro Leopoldo* (written between 1829 and 1834) and the *Saggio sull' istoria del cristianesimo nei primi due secoli* that he reveals himself as one of the most distinguished of the Italian Liberal Catholic school of historians. The promise of these works failed to be fulfilled in *Storia della repubblica di Firenze* (3 vols., Florence 1875; 2nd ed. rev. by the author, 1876; tr. into German, Leipsic 1876), the one work

which in spite of many interruptions Capponi ultimately completed and the value of which is vitiated by the lack of a fundamental unity of conception. His masterpiece was the *Frammento sull' educazione* (Lugano 1846; new ed. by E. Codignola, Florence 1921), the most original contribution to the theory of education made by any Italian during the first half of the nineteenth century. Firmly convinced that all human activity should be a form of self-expression, Capponi was an implacable critic of any pedagogic method which attempted to establish abstract principles for the development of the human spirit. All knowledge not rooted in the student's concrete experience was intrinsically sterile. No artifice, however skilful, could enable the educator to persuade the mind of his student unless he was himself thoroughly imbued with the ideas of which he was the mouthpiece. It was in the spiritual darkness of the modern world that the "art of empty words" and the "mechanism of methods" had been developed as a feeble substitute for the great intellectual ideals of former times which through their own inherent power had sometimes addressed and dominated "the minds of an entire people during an entire century." Nothing but the vitalizing influence of fresh ideas could cause education to become once more spontaneous and truly formative. Capponi's letters, rich in source material on the history of the Risorgimento, have been collected in six volumes by Alessandro Carraresi (Florence 1884-90). Most of his works are to be found in *Scritti editi e inediti di Gino Capponi* (2 vols., Florence 1877), collected by Marco Tabarrini.

CAPRIVI (DE CAPRARA DE MONTECULI), GEORG LEO VON (1831-99), German soldier and statesman. He served with great distinction as chief of staff of the tenth army corps in the Franco-Prussian war of 1870-71. In 1883 he reluctantly accepted from Kaiser Wilhelm I the appointment as chief of the admiralty. While in office he adhered to the policy of limiting the role of the German navy to the

modest one of coast defense. In 1888 he was relieved of his post in the admiralty by Kaiser Wilhelm II and appointed commanding general of the tenth army corps in Hanover.

On the dismissal of Bismarck in 1890 Caprivi was named imperial chancellor and served until 1894. When Caprivi assumed the chancellorship a problem of foreign policy of the utmost importance was pressing for settlement, the renewal of the so-called reinsurance treaty with Russia which Bismarck had made extreme efforts to secure and which was much desired by Russia. Caprivi, who was quite without political experience, followed the advice of Baron von Holstein, secretary for foreign affairs, and permitted the treaty to lapse.

During the chancellorship of Caprivi Germany secured Heligoland from England in exchange for Witu and Zanzibar. New commercial treaties were negotiated with Austria-Hungary, Italy and Belgium. These treaties were designed to advance the interests of business and trade and aroused the violent opposition of Prussian agricultural interests. The most important measures of Caprivi's period of office bore upon the development of the army. In 1893 he introduced experimentally the two-year term of military service in place of the three-year term. This act was vigorously opposed by the army. Further opposition was aroused in 1894 by his unwillingness to take severe measures against the Social Democrats and finally led to his retirement from office.

Caprivi was a man of great simplicity of character with an unwavering sense of duty. Essentially fitted for a soldier's career, he was twice, by tragic circumstance, drafted into high offices for which he did not feel himself adequately equipped but which as a loyal subject he felt forced to accept. His speeches for the years 1883-93 were collected by R. Arndt (Berlin 1894).

CAPTAIN OF INDUSTRY. The term "captain of industry" came into current use in the late nineteenth century to designate a presumptively leading figure in capitalist organization. The metaphor in popular usage expresses the need in an era of business dominance to set up personal figures who might carry some part of

the sentimental burden that had been borne in earlier ages by the military commander or the titled aristocrat. The concept of captain of industry was taken over by economic science in the course of the reaction against the excessively mechanized formulae of the classical and neo-classical schools. The captain of industry may be merchant prince or financial baron, cotton lord or railroad king. What is essential is that he should win his fame in money making or business activity, that he should stand out above his fellows by the size of his fortune, the power that he wields and the leadership that he exercises.

Although he is predominantly a modern figure he has put in an appearance wherever business organization has existed. Thus traces of his presence are found in Greece and Rome. During the Middle Ages he disappeared, but from the twelfth century onward he was found with increasing frequency in the fields of money lending and trading wherever there was a break in the old local, self-sufficient economy. The names of the Medici, the Fuggers, the Bardi, the Peruzzi, Jacques Coeur, are perhaps the best known of the period before the eighteenth century, but they were only the giants whose greatness has somewhat obscured the eminence of others.

The late eighteenth century marks the beginning of the modern period for the captain of industry. For the first time men in significant numbers were making fortunes in manufacturing, and among them some stood out sufficiently to deserve the title of captain: John Wilkinson the iron master, Boulton of the firm of Boulton and Watt, Wedgwood of the potteries, Tubeuf of the French coal mines, possibly Arkwright in the textiles, certainly, of a little later period, Brassey.

From this time on there has been no country of western Europe or America where capitalistic organization prevails, scarcely a field of economic activity, that has not at one time or another made its contribution to the roll of names of captains of industry. While the captain has been most conspicuous in the United States, his place in the economic life of England and Germany is only slightly less marked.

Questions at once suggest themselves as to what determines the time and place of his appearance, since he has never at any single time been found in all the fields under the domain of business. Is it mere chance that sets him up first in one place, then in another? Are there certain industries which by their nature

are predisposed to produce or receive the captain? Are there stages in the growth of any industry—infancy, for example, or overgrown boyhood—with which he is likely to be associated? What brings him more often to one country than to another? Innate differences in the character of the people, as Sombart ably if somewhat unconvincingly suggests? Or differences in economic organization and the rate at which industrialization has taken place? The times when captains of industry have become most conspicuous in any country seem to have been periods of most rapid industrial development and their greatest prominence seems to have been attained in those countries in which industrialization has come most rapidly. But this raises the question whether the captain of industry is the cause of rapid industrialization or merely one of its effects. If his role is causal, is this sufficient to account for the differences between countries or have differences in the political organizations and cultural backgrounds of the countries themselves played a part not to be ignored? Has the absence of a ruling class and its traditions in the United States, for example, had something to do with the number of great industrialists as well as with their peculiar behavior?

A question at once arises concerning the role played by the captain of industry in the development of capitalism and industrialism. Unfortunately the economic historian has paid little attention to this question and as a consequence only the most tentative conclusions can be put forward.

The function of business men as a group in the growth of capitalism may first be considered in connection with the conversion to business organization of industries previously under some different form of control. Here fortunately there is general agreement. No one appears to doubt that the business man was the active agent in this conversion, either by putting his gains acquired in one field to use in another or by securing funds from others which he could use in ways not common in the industry of the time. The process has been most clearly traced in agriculture and the textiles but it was evidently going on in other fields as well.

When one turns to the special role played by the captain of industry as distinguished from his anonymous fellow business men the case appears far less certain. There is, however, little evidence that he had a distinctive part or that he was more active than the men of lesser for-

tunes either in borrowing and using or in financing. In coal mining, if anywhere, he might be expected to be found, as coal operations even before the industrial revolution required relatively large amounts of capital. In spite of the formation of joint stock companies the men who took part in the early capitalistic organization of the coal industry were probably drawn from the wealthier groups of entrepreneurs of the period, but who can say that the leading captains of industry concerned themselves with the fortunes of the industry? In the textiles, on the other hand, the evidence is quite clear that the men most active in promoting change were merchants with modest fortunes and masters who stood only slightly above their fellows. It is not at all clear that the spread of capitalism from one industry to another was appreciably speeded up by the rise of captains of industry.

Capitalism also spread by new industries rising under business organization. Here the question of the role of the business man in the growth of capitalism merges into the question of his role in the development of industrialism, and the two can best be considered together in connection with the rise of new industries. There is no such agreement about the role of the business man in this field as in the conversion of industries to a capitalistic basis. It is easy to draw a picture of the business man, especially the big business man, restless, active, ever seeking new opportunities for gain, new lines of activity. In fact this picture has been drawn so often that the captain of industry has appeared to be the sole promoter of new industries. There are obvious elements of truth in the picture; but it is after all only a partial picture. There have been times when the business man has been lethargic or indifferent and has had to be prodded into action. In the United States and in France, for example, the business man was a familiar figure before the railroads were built. Yet it was not the business men who took the initiative in their building, until rather rich inducements were offered by local or central government. It is obvious that where business organization is thought of as the natural if not the only way to organize industries business men must become interested in new lines of activity before new industries can be developed. The point is, however, that it has sometimes been necessary for others to point out to them the golden opportunity that lay open in developing new industries.

The special part of the captain of industry is

less certain. Has he been more active than the general run of business men in promoting new industries and is this one reason for his greater success? Would his absence have meant a slower industrial development? Examples can be given where the answer clearly is yes. Boulton in the eighteenth century, Emil Rathenau and Henry Ford in the twentieth, not only won their fame from work with infant industries but as nearly as can be determined appreciably hastened the establishment of these industries on a firm basis. Furthermore, it is hard to believe that without these men the industrial development of their respective countries would not have been retarded.

On the other hand, it is not hard to find captains of industry who were not connected with new industries and to whom the newer industries of the time owed little. Harriman, Stinnes, Gary, may be mentioned here. Furthermore, not every new industry can be traced to some captain of industry. If the industries fathered by some industrial chieftain are either more numerous or more important than those whose origin is more obscure, this fact has not been established. Or if the activities of those captains who have not been concerned with promoting new developments have indirectly stimulated the growth of industry, this too is yet to be established.

In one field, however, there seems little question concerning the distinctive role of the captain of industry, and that is in the development of backward regions that knew neither capitalism nor industrialism. Here apparently his influence is so pronounced that it is slight exaggeration to say that without his efforts the heathen might have been left for generations in his blindness with no chance to worship smoke and steel.

Another question concerning the role of the captain of industry in the development of industrialism relates to the improvement of technological equipment. It seems clear, widely held theories to the contrary notwithstanding, that the captain of industry has neither consistently favored nor consistently blocked technological change. Rather his influence has been now in one direction, now in another, depending on many factors, among which his estimate of the relative profits to be gained from speeding or retarding change has always been important and often controlling. The records, however, as they have been compiled and analyzed, do not show in which direction he has leaned most frequently. They furnish some clear examples

of outstanding business men who have actively promoted improvements in production and equally clear examples of industrial leaders who have been indifferent, if not hostile, to new inventions. On their face perhaps the records suggest that the former position is the more common, at least for the captains of industry. But so much of the evidence has been compiled by men who have never questioned the divinity of their gods that the point is far from established.

The influence of the captain of industry is more certain if we turn to the form of organization. It is obvious that his influence has always been toward increasing the size of the business unit. He has not only created large and ever larger enterprises of his own but his success has encouraged others to do likewise, so that even if his own establishment goes to pieces he leaves a permanent impress on industry. Here his contribution has been distinctive; it is hardly too much to say that every signal increase over the customary size of the business unit shows the handiwork of some captain of industry.

With the increase in size of the business enterprise have gone interesting consequences, of which the more obvious are increased possibilities for large scale or mass production. It should not be supposed, however, that an increase in the scale of production follows immediately or even inevitably upon an increase in size of the business unit. It is often true that for years after consolidation of financial operations under a single control no change is made in the size of the productive establishment. But among the contributions of the captain of industry should be set down the large business enterprises which have made for conditions favoring mass production and machine technique. Thus even those captains of industry who were themselves indifferent to technological advance indirectly at least did something to promote it.

Sometimes too the concentration of many business ventures in an industry under a single control has brought elements of order where chaos had prevailed. This would be stated differently by those whose faith rests in the unseen order of free competition. To them the dominant position of a single firm represents not a step toward order but the emergence of the trust problem.

In the hands of the captain of industry the business enterprise has not been confined to a

single industry. Especially in more recent years a characteristic of his operations has been the union of alien activities under a single control. Sometimes the activities and their unification have brought about that integration of industry which is such a marked feature of recent industrial development. At other times there seems to have been no pattern followed in extending into various fields, but the union which resulted must be accounted for by the chance of the moment or by the personal interests of the captain of industry. The integration of industry may, as some think, mark a new and desirable stage in industrial organization; in this event the captain of industry must be given credit. The concentration of control with no basis in industrial processes can only represent confusion. And this too must be set down to the account of the captain of industry.

Whatever his role in industrial development, the captain of industry as a figure prominent in the popular imagination has played an important part in social and political life. As a social figure he has often exhibited spectacular, and sometimes vulgar, ostentation. He has helped to extend the range of the canon of conspicuous waste. His intervention in the political life has often exhibited a sense of superiority to the current rules of political morality and even to the law. Often in America at least he has been found, and more often suspected of, dictating his will to officers of the state or corrupting them with his gold. Often he has shown such slight sense of responsibility for the well-being, so little regard for the human rights, of the workers in his establishments that he has almost become a symbol of the oppressive employer. On the other hand, the captain of industry has often exhibited a generous public spirit. He has often stood out as a patron of the arts or sciences; he has contributed freely for broad humanitarian purposes, and the cases are not rare in which he has been active in movements for better government. Often he has taken a genuine interest in the welfare of his employees, and if this interest has too often taken a paternalistic turn, the captain of industry who understands and respects the ideals of organized labor is by no means unknown.

In spite of the general interest in the captain of industry very little is known as to the real character of the type—if it is indeed a type. We have of course a large and growing number of biographies of industrial leaders, but these either deal so exclusively with externals that

they tell little of character or, if they attempt to give qualities, are so obviously cut from a standard pattern that they tell more of the biographer or of the prevailing legend than of the captain of industry. We have also generalized descriptions of the entrepreneur, with suggestions that the captain of industry is this type raised to its highest power. Some of these generalized descriptions are extraordinarily interesting and list many of the qualities that one would expect to find characteristic of captains of industry from the nature of their activities. But the descriptions stop with listing qualities; they do not for the most part even try to point out the special combination of qualities which distinguish the industrial leader and without which no man can become a captain of industry.

It is often suggested that the conditions which have brought the captain of industry into prominence are passing and that he is destined to take his place, as a purely historical figure, alongside the knight and nobles of an earlier age. The scale of industrial and business activity has already become so vast that it is perhaps becoming impossible for one man to win a position of dominance. Organization is becoming so complex that possibly it can be run only by cooperation of specialist with specialist. It may be that a bureaucracy is about to replace the outstanding leader. On the other hand, new men may arise who are able to use the bureaucracy for their own ends or who even as part of the bureaucracy will stand out above others quite as distinctly as a captain above his men. At the present time it is impossible to say whether the captain of industry has seen his day or will in the future compare with those of the late nineteenth and early twentieth century, as a Gary with a Wilkinson, a Rockefeller with a Tubeuf or a Morgan with a Fugger.

CARAFFA, GIOVANNI PIETRO. See PAUL IV.

CARBONARI was the name of a secret society which spread throughout Italy and France during the period following the Treaty of Vienna as a protest against the attempt of the Holy Alliance to reestablish the political situation which had existed before 1789. According to the treaty

the Bourbons, represented by Louis XVIII, were restored in France. In Italy the kingdoms established by Napoleon were effaced and the peninsula was redivided into a group of petty states. Lombardy and Venetia were governed directly by Austria; Austrian princes ruled in Modena, Parma and Tuscany; Piedmont, while governed by a native ruler, Victor Emmanuel I, was subject to defensive and offensive alliances with Austria; and the Bourbon Ferdinand returned to his Neapolitan throne under a secret pledge to Austria that he would introduce into his kingdom "no principle irreconcilable with those adopted by His Imperial Majesty in the government of His Italian kingdoms"—an unnecessarily indirect endorsement of absolutism. In order to perpetuate its reactionary regime the Alliance instituted an elaborate police system and summoned a series of congresses through which the powers acted "in concert" to suppress dangerous movements. What the Holy Alliance sought to do was to obliterate the traces of liberalism left by the French Revolution; what it actually accomplished was to drive them under cover. The secret society became the customary refuge of revolutionary ideas, not merely because it was secret but because it offered as a counterpoise to the elaborate organization of the Alliance the advantage of cooperative activity. The Carbonari was the most prominent of these societies.

At the beginning of the restoration period Italian Carbonarism had achieved, within a small sphere, a definite organization and had evolved certain political ideals which, although vague and abstract, were to dominate it throughout its existence. This evolution had taken place in the kingdom of Naples under the Napoleonic regime of King Joseph and of Joachim Murat.

As the masons' guild was the prototype of freemasonry, so the charcoal burners' guild of the French forest was the prototype of Carbonarism. The latter first manifested itself as a political force in the province of Franche-Comté during the last years of the old regime and the early years of the French Revolution, when the "Bons Cousins Charbonniers" borrowed the ritual of the ancient guild and formed an association for corporate defense, which became a vehicle of revolutionary ideology. Introduced into Naples about 1806, perhaps through the journalist P. J. Briot, who had been a "Bon Cousin," the society developed into a formidable center of opposition to Napoleon. Spreading first among the disaffected officers of the Grande

Armée, where secret societies of a masonic character had long flourished, it soon found willing recruits among the native classes, particularly the landed property holders and priests, who had suffered most from the advent of Napoleon. The Neapolitans were quick to accept the revolutionary, quasi-republican catchwords of the French—an ideological heritage which they were never to outgrow; but as Carbonarism fashioned new bonds, cutting across class and local divisions, they began to nurture the first seeds of nationalism. At the same time, under the influence of the Spanish liberal rising of 1812 and the English rule in Sicily, their amorphous ideals of universal brotherhood and enfranchisement became transformed into a somewhat more specific demand for constitutional government. Thus it was within the ranks of the Carbonari that the two ideals which were to remain the constants of the political thought of the Risorgimento—Italian unity and constitutionalism—had their opaque inception.

When the Napoleonic regime ended and the restoration period began, Carbonarism as it had been organized in Naples spread to other parts of Italy: to the Papal States, where it struggled for its existence against the arch-statesman Consalvi; to Piedmont, where it recruited the students and younger members of the nobility, among whom it became something of a fashion; to Lombardy, where under the guidance of Confalonieri it became something of an intellectual creed; and in lesser degree to the other Italian states. Until 1820, however, the Carbonari remained little more than a threat, an intangible force which the various absolutistic governments now sought to conciliate, now sought to extinguish. Its political aims were entangled in a quasi-masonic ritual of signs, passwords and symbols and were imparted only to the higher orders, to which after a period of apprenticeship under oath of secrecy and obedience members might or might not be admitted. If the Carbonari stood for constitutional government, the exact nature of the fantastic constitutions which they hoped to build varied through every shade of republicanism and limited monarchy. They were equally unspecific about their ideal of Italian unity. Their organization, despite its vast pretensions, was loose, unstable and undemocratic. The lodges or *ventes* in each state were theoretically held together by a Grand Lodge, but schisms were frequent; and the organizations of the various kingdoms were

affiliated only by bonds of sympathy. Moreover, Carbonarism was at no time a popular movement. Its real tendency was to detach itself from the state and to provide a government for its own members, the great majority of whom were in fact drawn from the bourgeoisie. These, and the lack of practical leaders, were the weaknesses of the society. How fundamental they were was to become clear during the Carbonarist rising of 1820-21.

The first manifestation of the rising was in Naples. The Spanish liberal movement of 1820 had resulted in the granting of a constitution, which as prospective heir to the Spanish throne Ferdinand of Naples had recognized. Having at last discovered a definite symbol upon which their political mysticism could fasten, the Carbonari began to demand that Ferdinand grant the Spanish constitution to Naples. By the summer of 1820 their ranks had swollen to perhaps 300,000, consisting principally of small property holders whom the economic distress of 1820 had roused into action and the provincial militia, which since its organization in 1817 had been a stronghold of Carbonarism and which was now dominated by the Carbonaro Guglielmo Pepe and by romantic adventurers. Revolution independently precipitated by a regiment located at Nola spread throughout the kingdom, and Ferdinand, once more forced to bid for his throne, granted the Spanish constitution to Naples. It was after the assemblage of Parliament in October that the inadaptability of Carbonarism to political action was most strikingly revealed. Incapable, except for an insurgent group which demanded a republic, of extending their vision beyond the unworkable Spanish constitution or of providing their bourgeois constituents with much needed social reforms, unwilling to conciliate liberals like the minister Zurlo outside their ranks, powerless in the face of the mounting budget, the Carbonari rapidly lost their hold upon the people. Meanwhile, at the congress of Troppau in 1820 the Holy Alliance had signaled its intention to intervene in Neapolitan affairs; at the congress of Laibach in 1821 Ferdinand solemnly foreswore his oath to the Spanish constitution and consented that an Austrian expeditionary force be sent to Naples. When on the twenty-third of March the Austrian force, having defeated General Pepe's disheartened band at Rieti, entered Naples, the Carbonari had already disintegrated.

The course of the Carbonarist revolution in other parts of Italy is eloquent evidence of the

incapacity of the society for concerted action. Under the direction of Santa Rosa the Piedmontese Carbonari had been making more or less indefinite plans for revolution since 1820; but before launching their supreme attempt they were awaiting the word of the young heir to the throne, Charles Albert, whom in their weakness for hero worship they had taken as a symbol of liberalism. It was not until after Rieti that their revolution actually broke out, and then it needed only the duplicity of Charles Albert and a fresh Austrian expeditionary force to seal its doom. With the failure of the Carbonari of Lombardy the heroic period of Italian Carbonarism ended and the period of retribution under the strong hand of Austria began. Most of the prominent leaders were sentenced to exile or imprisonment. Only a few isolated incidents, particularly the risings in Modena and the Papal States after the French revolution of 1830, attested the continued presence of the Carbonari in Italy. Nevertheless, in the Italian imagination the ideas of independence, unity and liberty had become to a large extent associated with Carbonarism. Mazzini saw the weakness of the secret society as an instrument of revolution and in organizing Young Italy attempted to create a movement which should recruit the whole population without restriction of membership and which should have no secret in its doctrine. But the methods of Carbonarism infected Young Italy and it too developed into a secret society.

The last scene of the Carbonarist revolution was France. The French society was organized in 1820 by a group of young students, Bazard, Buchez, Flotard, Joubert and Dugied, who had already been affiliated with another secret society, the *Loge des Amis de la Vérité*. Besides students the chief elements in the French Carbonari were retired officers and soldiers of Napoleon, natural enemies of the Bourbon regime; members of the active militia, whom the peaceful policy of the government deprived of opportunity for occupation, glory and promotion; and liberal members of the professional classes. The society also gained the adherence of certain prominent radicals in the Chamber of Deputies: Lafayette, Dupont de l'Eure, d'Argenson, Corcelles, Koechlin and Beauséjour. The French Carbonari corrected certain of the weaknesses of the Italian society. They discarded part of its ritual, particularly the religious elements; and in theory at least they created a more democratic, more closely knit organization. A definite hierarchy corresponding to the vari-

ous political divisions of the nation—commune, canton, department, etc.—was headed by a *vente suprême*, which theoretically determined the policy of the entire society through a system of congresses. Nevertheless, the Carbonari failed in France as ignominiously as in Italy. The only common sentiment among the various groups in its composition was hatred of the Bourbon regime; beyond that their allegiance was divided among republicanism, Bonapartism and Orléanism. An attempt was made to find a least common denominator of political principle in the constitution of 1791; but such a program satisfied no one in particular and won only perfunctory acceptance. The standard raised by the Carbonari was that of revolution pure and simple, not of social reform. Hence the masses stood inertly by, permitting the official police and military forces to hold the Carbonari in check. Between December, 1821, and July, 1822, eight conspiracies organized in various sections of France—in Paris, in the departments of the east and southeast, in Normandy and along the Loire—were speedily suppressed, and by 1823 the society had completely disintegrated and dispersed. What it left in its wake was a memory sanctified by the martyrdom of its defeated conspirators—General Berton, Colonel Caron, the four sergeants of La Rochelle—and an indelible impression upon a group of young men, former Carbonari, who were to play an important part in subsequent French history. Buchez, Bazard and Chevalier were disillusioned by their experience and passed over to Saint-Simonism. Others retained their faith in the secret society as a revolutionary force and formed an association which became the nucleus of another society of the restoration, Aide-Toi, Le Ciel T'Aidera. Some republican societies of the July Monarchy were descended in both personnel and ideology from the Carbonari.

GEORGES BOURGIN

See: SECRET SOCIETIES; REVOLUTION; CONSPIRACY; CONSTITUTIONALISM; NATIONALISM; REPUBLICANISM.

Consult: Bourgin, Georges, *La formation de l'unité italienne* (Paris 1929); King, Bolton, *The History of Italian Unity*, 2 vols. (London 1899) vol. i, ch. ii; Dito, Oreste, *Massoneria, carboneria ed altre società segrete nella storia del risorgimento italiano* (Turin 1905); Johnston, R. M., *The Napoleonic Empire in Southern Italy*, 2 vols. (London 1904) vol. ii; Mathiez, Albert, "L'origine franc-comtoise de la charbonnerie italienne" in *Annales historiques de la révolution française*, vols. i-vi (Reims 1924-29) vol. v, p. 551-61; Calmette, A., "Les carbonari en France sous la restauration" in *La révolution de 1848*, vols. i-xxv (Paris 1904-29) vol. ix, p. 401-17, and vol. x, p. 52-73, 117-37, 214-30.

CÁRDENAS, FRANCISCO DE (1816-98), Spanish jurist. His first contribution to the study of Spanish law was a series of essays in *El derecho moderno*, many of which were subsequently collected and published as *Estudios jurídicos* (2 vols., Madrid 1884). He demonstrated his ability as a jurist in his report on the reform of the civil code in 1850 and by his substantial share in the drafting of the current Spanish mortgage law. Cárdenas was affiliated with the conservative party and held many important political positions, including the ministry of justice in the cabinet of Cánovas del Castillo in 1874.

His work "Algunas noticias acerca de los progresos y estado actual de la legislación civil y penal de Inglaterra" (Real Academia de Ciencias Morales y Políticas, *Memorias*, vol. ii, 1867, p. 285-301) and the *Estudios jurídicos* are scientifically interesting, but his most important work is the *Ensayo sobre la historia de la propiedad territorial en España* (2 vols., Madrid 1873-75). This history runs from early times down to the first years of the nineteenth century. The section on mediaeval law, dealing with the feudal system, manorial estates, free cities and Muslim law, was completely superseded by the more recent researches published in the *Anuario de historia del derecho español* (vols. i-vi, Madrid 1924-29), but interest still attaches to parts of the second volume devoted to church property and the influence of the laws of primogeniture on property entailment. Cárdenas' "Estado de la población y del trabajo en las islas de Cuba y Puerto Rico" (Real Academia de Ciencias Morales y Políticas, *Memorias*, vol. iv, 1883, p. 419-54) is important for a critical appreciation of the socio-economic status of the natives and contains valuable data on the agrarian economy and the production of the cane sugar mills in those countries as compared with British Guiana or Barbados, where free instead of slave labor was used.

FERNANDO DE LOS RÍOS

CARDOZO, JACOB NEWTON (1786-1873), American editor and economist. Cardozo became acting editor of the *Southern Patriot* (Charleston, S. C.) in 1817, and from 1823 to 1845 was its proprietor. Although the journal was a recognized free trade organ Cardozo used it in 1822 to support Congress in its retaliatory measures against Great Britain's closing the West Indies to American trade. In 1827 or 1828, at the request of the Charleston Chamber of

Commerce which he had helped to revive, he drew up what he believed was the first memorial from the South protesting against the "Bill of Abominations." Cardozo did not participate, however, in nullification.

In his *Notes on Political Economy* (Charleston 1826) Cardozo sought to refute the Ricardian teachings of John McVickar's *Outlines of Political Economy* (New York 1825). Cardozo was unwilling to have American statesmen guided by the doctrines of the European classical school, which were pessimistic not from the nature of economic law but because of "a vicious social organization." America, "whose institutions and laws have done less to derange the natural order of things," was, he felt, a better place for the investigation of economic laws. Cardozo criticized the Ricardian rent theory and the Malthusian principle of population, connecting increase in population with improvements in agriculture, not with decreasing returns from the soil. To this extent he may be considered a member of the American nationalist school, of which Daniel Raymond was an earlier proponent and Henry C. Carey the later leader. He differed from them, however, in his vigorous advocacy of free trade.

BROADUS MITCHELL

Consult: Elzas, B. A., *The Jews of South Carolina* (Philadelphia 1905) p. 176-79; Turner, J. R., *The Ricardian Rent Theory in Early American Economics* (New York 1921) p. 75-82.

CARDUCCI, GIOSUÈ (1836-1907), Italian poet and literary historian. He was born in Valdicastello and in 1860 became professor of Italian literature at the University of Bologna, where he remained until his death. He was the last of the great classic poets of Italy: a dreamer and idealist, a man of deep moral feeling as well as of a profound sense of sorrow and of love, who clothed his emotions in simple, vigorous forms enriched by living knowledge of the history of art. These qualities are revealed most clearly in the lyrics of his maturity: the *Rime nuove* and the *Odi barbare*. A more practical aspect of Carducci's activity was his role in the political and moral life of Italy after its unification. Absorbing the spiritual tradition of the Risorgimento he presented patriotism not in a nationalistic light but precisely as a moral force permeating the life of the whole community and contributing to its continuous progress toward higher forms. Carducci was democratic and yet at the same time attached to the past: herein lies

the key to the evolution of his political views. In his youth he was a republican, a follower of Mazzini and Garibaldi, passionately devoted to Rome, which in those years had not yet been restored to Italy. In later life he came to understand and to acclaim the significance of the monarchy of Savoy, which had forged a bond between the old Italy and the new, had combined political wisdom and military strength with constitutional government and liberty and had unified Italy. His work as a moral educator constantly fostering, by work and example, the qualities of simplicity and strength was in harmony with this imaginative political idealism, as were his investigations as scholar and teacher into the entire history of Italian literature. Carducci's *Opere* have been collected in twenty volumes (Bologna 1889-1909) followed by one volume of works published posthumously and two of letters.

CAREER. This term is applied to any continuous and conspicuous work in which notable achievement may be won. Its scope changes inevitably with changing institutions, activities and values. What constituted a career in the Athens of Pericles, in the mediaeval church, in Victorian England or in twentieth century America varies as widely as the civilizations themselves. Careers, in other words, have as much to do with the particular social arrangements of the era in which the individual finds himself as with the possession of "innate" talent.

Every age holds in high regard certain fields of activity in which special recognition may be won and also determines by its institutions who shall be eligible to compete for its prizes. The gifted business executive cannot, under the Soviet system, achieve a career as a private capitalist. He may, however, have a career of honor and fame in serving the state. Even in the arts, in which talent would seem to be the one necessary qualification, the possibility of a career depends upon many factors in the social situation, particularly the specific arrangements for the stimulation and reward of talent. Patronage and support may come from rulers, courts, church, nobles, political parties or the general public at

large, but whatever the arrangements for support, careers in art must depend upon and vary with them. And the same is true of careers in general. Whether the system be one of communism or caste, democracy or status, careers are determined by the repute in which different services are held by the community and the support provided for them.

The growth of political and social democracy has had notable effects both upon the conception of career itself and upon those social arrangements which determine the opportunities for careers. The Napolconic era defined democracy as a condition in which "the career is open to talent," and although it failed to achieve this goal the idea has been one of the guiding principles of all democratic movements. Moreover the tremendous economic changes of the past century have swept away many of the old barriers; and today the demands of the machine age call for talent wherever it can be found, irrespective of class, race or creed. The necessities of industrialism have been gradually breaking down the age long prejudices against certain forms of work which have existed for centuries in different countries and among different races. One recalls the exclusion of the Thelban shopkeepers from the magistracies, and the law which forbade the Spartiate to engage in any pecuniary occupation whatever.

This tabu against commercial and industrial employments Veblen explores in his *Theory of the Leisure Class* (New York 1899), pointing out that the normal and characteristic occupations of the upper classes have been government, war, devout observances and sports, and that the more any work has to do with the immediate concerns of getting a living, "elaborating the material means of life," the less honorable it is. Certainly the distinctions between occupations with respect to honor, which Veblen traces back to the distinction made in barbaric times between exploit and drudgery, have with diminishing force persisted even down to our own day. In early modern England, when the aristocracy held a monopoly of political power, careers were identified almost entirely with government posts and were open only to the upper class or to those of the middle class who were elevated to the peerage. Younger sons were indeed sent into trade and the professions, a practise sharply contrasting with that of the continent, where every scion of an aristocratic stock was expected to hold aloof from the vulgarities of trade. The stricter English aristocrats shared the continen-

tal dislike of trade and looked with little less scorn on the professions, with the exception of the army and the higher grades in the church. Foreign trade, it might be noted, was held in far greater respect than domestic, and wholesale was more favorably regarded than retail. The waning of the political power and privileges of the aristocracy manifested itself in a change of attitude toward occupational activities. Certain professions, like law and medicine, came to be more highly regarded, as they had long been in Scotland, where every ambitious family was ready to incur heavy sacrifices in order to give the most gifted son the education which would enable him to enter one of the learned professions.

How limited was the field for careers in England as late as 1855 is seen in the report of that year on the *Reorganization of the Civil Service*, in which the need for new careers was emphasized. "Everyone who has had to advise . . . knows how extremely and increasingly common is the case of those young men who scruple to take Orders, have no chance at the bar, and yet possess that kind of ability, and that amount of attainment, which would be inapplicable to engineering and thrown away upon farming. . . . I have known young men, neither ignorant, nor dull, nor idle, nor dissipated, who yet, for want of one more profession to choose from have been condemned to years of inactivity, with little or no fault of theirs."

There is a sharp contrast between this situation and that existing today in America where the field for careers is practically coextensive with the entire field of activity. Conspicuous success in almost any occupation is tantamount to a career, whether it be in the professions or in business. The merging of the conception of career with that of pecuniary success has been accomplished partly by the elevation of business in the general esteem, partly by the devaluation of the non-pecuniary elements in the traditional career. While it is not true that honor is accorded to callings precisely in the measure of their lucrativeness, that the real estate dealer and the artist are reduced to the common scale of money income, nevertheless there is a closer approximation to this condition in America today than has ever appeared in any of the older countries. Conventional patterns of achievement have been broken down, and the man who "makes good in his own line" wins his place in the community. Moreover, America has been par excellence the land of entrepreneurial opportunity; and the

prevailing doctrine of the essential harmony of private and public gain has given to individual success the stamp of public approval.

The most conspicuous extension of the conception of career in the twentieth century and a further step in its democratization is its application to women's work. At the outset of the feminist movement there was a presumption that only the woman with exceptional talent—the great actress or the great singer—was justified in having a career, with all that it meant in the repudiation of ordinary domestic and family duties. Today, however, the term is used for any self-supporting business or professional position outside the home. Outstanding talents and gifts are not required. A career for women has come to mean the carrying on of distinctive individual activity as against being merged in the family group. The causes of this change in woman's status must be sought in the industrial and social changes which have taken to the factory so many of the domestic processes normal to the home of fifty years ago, in the revolutionary changes in women's education and in the feminist movement, which is partly cause and partly effect, registering as well as initiating change.

One of the essential problems of democratic social policy is that of the discovery and reward of talent. The outstanding feature of a democratic scheme of education is that on the widest possible scale it provides for the discovery and training of ability in different fields. The working out of this tendency can be seen in the growing substitution of individual training for rigid classroom methods, in the development of personnel studies and in the building up of schemes of vocational guidance whose aim it is to bring human beings and jobs into such fruitful relations that careers will be opened to the talented and that those without talent may find their most useful place. Here as elsewhere in social theory there is a cleavage between those who would trust largely to the forces of the market place to achieve a nice discrimination in this matter and those who assert the need of conscious purposive control. The advocates of control maintain that the discovery and training of talent as well as its support must be the object of social planning if a society is properly to provide for the maintenance of careers which are essential to its own successful living.

RACY; BOURGEOISIE; BUSINESS; PLUTOCRACY; WOMAN, POSITION IN SOCIETY; VOCATIONAL GUIDANCE.

CAREY, HENRY CHARLES (1793-1879), American economist and publicist. Retiring as head of a Philadelphia publishing house in 1835, Carey thereafter devoted himself mainly to economic studies and became an outstanding antagonist of the current English political economy. His fundamental postulate was the unity of the laws of nature. Social science was conceived as the discovery of those laws by the application of which man may improve his conditions through the development of human association and individuality. Carey's theory of value, central to his system of thought, is substantially a labor-cost theory. But stressing dynamic improvements in man's power over nature he explained the ratio of exchange, derived from a reciprocity of services ("labor saved"), as expressing labor costs of reproduction. Applied as a universal law to all cases of value (excluding labor), it included land, thus making of rent merely a special case of interest. While the gross returns from land were asserted to rise progressively with the historical movement of cultivation from poorer to better lands, the share of output returned as land rent was to fall with the progress of civilization. Carey denied the Malthusian doctrine and sought to establish a principle of increasing relative remuneration to labor as compared with that of capital.

In its entirety his system was one of economic harmonies comparable to that of Bastiat, whom Carey accused of plagiarism. Philosophically Carey represented essentially a return to Adam Smith; nevertheless he advocated a system of tariff protection. Carey's intellectual associations were most diverse. But his thought is less important as an example of intellectual trends than as a demonstration of the inapplicability of the Ricardian economics to American circumstances. Impressed by America's abundant resources and hopeful prospects Carey attacked the dynamic implications of the Ricardian system. If his protectionism appears as an unconscious deference toward a rising industrialism, his economic philosophy is nevertheless essentially agrarian, stressing the overwhelming importance of a prosperous agriculture.

Carey's writings ran to thirteen volumes and endless pamphlets and articles. He was the first American economist to win a following abroad and was the center of a controversy in which Max Wirth, Eugen von Dühring and Francesco

Ferrara tried to defend his system against the attacks of Lange and Held. His principal books were translated into nine languages and his influence was probably greater abroad than at home.

Carey and his Social System" in *Political Science Quarterly*, vol. v (1890) 553-82.

CAREY, MATTHEW (1760-1839), American editor, publisher and economist. Carey, a native of Ireland, came to Philadelphia in 1784 after being convicted for libelous criticism of the Irish policy of the British ministry. Here the "persecuted printer" was introduced to Lafayette, whose financial assistance gave Carey his start in American journalism. As editor of the *American Museum* he became identified with the political life centering in Philadelphia. In 1791 he entered the bookselling and publishing business, eventually making the firm of Carey and Lea the chief publishing house of its time. After organizing in 1819 the Philadelphia Society for the Promotion of National Industry he retired from business to become an early champion of the "American system" for the promotion of domestic industry. Under the auspices of this society, which patronized Friedrich List during his American residence, Carey published most of his writings.

Carey's first work of general interest was *The Olive Branch* (Philadelphia 1814; 10th ed. 1830), an effort to harmonize the factional interests during the War of 1812. *The New Olive Branch* (Philadelphia 1820; 2nd ed. 1821) is an impassioned commentary on the ruin spread among American industries by the heavy influx of European goods after the Napoleonic wars. Its main burden, taken up repeatedly throughout his many tracts and his *Essays on Political Economy* (Philadelphia 1822), is the need of protective tariffs to encourage American manufactures and to expand the domestic market for raw materials. In addition to the tariff he

urged a program of internal improvements to achieve an economic "harmony of interests" conducive to the preservation of the Union. In the less important of his pamphlets, some of which were published anonymously or under various pseudonyms, Carey dealt with such public questions as banking and currency reform, factory labor, immigration, charities and religious liberty.

A. D. H. KAPLAN

Consult: Bradsher, E. L., *Mathew Carey*, Columbia University, Studies in English, 2nd ser., no. xix (New York 1912); Maier, E. F. J., in American Catholic Historical Society, *Records*, vol. xxxix (1928) 71-154, containing bibliography.

CARLE, GIUSEPPE (1845-1917), Italian legal philosopher. Carle became professor of the philosophy of law in the University of Turin in 1872 and was later senator of the realm. Following in the path of Vico, Romagnosi and Gioberti he turned from the metaphysical abstractions and exaggerations of Spencerian positivism to the historical and psychological method grounded in the methods and findings of the social sciences, which he was among the first to introduce and apply in Italy. In his *La vita del diritto nei suoi rapporti colla vita sociale* (Turin 1880, 2nd ed. 1890) he discussed law in its relation to the life of society, examining the latter in its three stages, patriarchal organization, city-state and modern national state. In *Le origini del diritto romano* (Turin 1888) he reconstructed organically, by sociological methods, the primitive Roman law and showed that the formation of Rome and of its law was not the outcome of a process of true evolution but rather the result of a selection of elements inherent in the gentile organization. In *La filosofia del diritto nello stato moderno* (Turin 1903), of which only one volume was published, he laid the foundations of a system of legal philosophy sufficiently comprehensive to meet the requirements of the modern nation state, and particularly of the new state of Italy. Like Gioberti, Carle had a vital conviction of Italian supremacy in juristic and social studies and like his teacher, Mancini, he stressed nationality as the basis of the modern state.

G. SOLARI

Consult: Solari, G., "La vita e il pensiero civile di Giuseppe Carle" in R. Accademia delle Scienze di Torino, *Memorie*, 2nd ser., vol. lxvi (1926) no. 8.

CARLETON, GUY, FIRST BARON DORCHESTER (1724-1808), British soldier and colonial administrator. He governed Canada from 1766 to

1778 and, after having served as British commander-in-chief at the close of the Revolutionary War, from 1786 to 1796. The beginning of the office of governor general may be traced to his appointment in 1786 as governor not only of Canada but also of Nova Scotia, New Brunswick and Prince Edward Island in order to consolidate what was left of British North America after the wreck.

His influence is still felt through the Quebec Act (1774), for which he has been held chiefly responsible. This act was based on his assumption of the impossibility of imposing British institutions upon the Canadians, who were at that time almost all French, and on the failure to attract more than a few hundred English speaking urban settlers to the country. In the face of the troubles with the old colonies Carleton sought to win over the Canadians by giving them a constitution that they desired. Because the Quebec Act guaranteed them their religious system and their civil law French Canadians today regard it as their charter of liberties, but at the time the clergy and the *seigneurs* were the only classes in Canada which welcomed it, because Carleton committed two errors. Failing to perceive the emancipating influence of frontier conditions he aimed at controlling the *habitants* through the *seigneurs*, thus arousing the resentment of the former. He also alienated the small but influential English speaking mercantile minority by disobeying the home government's instructions to modify the legal system in their favor. The consequent discontent opened Canada to invading armies from the revolting colonies, where the act was considered one of the "Five Intolerable Acts," and also contributed to the racial strife of the early nineteenth century.

CARLI, GIAN RINALDO, CONTE (1720-95), Italian economist, poet and scholar. He was born in Capo d'Istria and in 1753 moved to Milan, where eighteen years later he became president of the Council of Finance. In this capacity he assisted in abolishing many abuses and carried out

a complete reformation of the coinage system according to a plan he had previously proposed in his *Osservazioni preventive al piano intorno alle monete di Milano* (Milan 1766). A man of catholic interests and knowledge Carli devoted much attention to monetary questions. Included in his great *Delle monete e dell' istituzione delle zecche d'Italia* (4 vols., Venice 1754-60) is the essay *Del valore e della proporzione dei metalli monetati con i generi in Italia*, in which he compares the purchasing power of a unit of money at the time of the discovery of America with that of the same unit in 1750. By showing that the bullion content of the monetary unit had decreased Carli refuted the theory of contemporary economists that the trebling of commodity prices indicated a corresponding increase in the quantity of metal in the country. In his *Breve ragionamento sopra i bilanci economici delle nazioni* (1769) he criticized vigorously the doctrine of the balance of trade. His observations on the non-commodity items which must be included in computing the balance distinguish him as a pioneer of a new conception, the balance of payments. Carli was not, however, a free trader and in his *Del libero commercio dei grani* (Milan 1771) he strongly advocated government regulation of the grain trade, pointing out that the question must always be settled on practical rather than theoretical grounds. Important among his other works was *Relazione del censimento dello stato di Milano* (1776), containing a critical history of methods of evaluating property and an analysis of the newly established Milanese county council which reveals Carli's sympathy with the division of society into social classes. Carli's interest in American politics and economics was manifested in *Delle lettere americane* (2 vols., Florence 1780; new ed. 4 vols., Milan 1786). Some of Carli's works have been republished in the Custodi collection.

ROBERTO MICHELS

CARLILE, RICHARD (1790-1843), English social reformer, free press agitator, pioneer in the birth control movement and editor of free thought periodicals. Carlile became perhaps the most daring of Francis Place's disciples in the

British birth control agitation of 1825-30. His chief work is probably the pamphlet, *Every Woman's Book; or, What is Love?* (London 1826), the first tract in the English language devoted exclusively to the medical as well as to the social and economic aspects of contraception. Although short lived it was widely distributed; its influence upon Robert Dale Owen and through him upon the founding of the American birth control movement was not inconsiderable.

Carlyle's efforts in behalf of the liberation of the English press, which began in 1817 with the attempt to revive the influence of Thomas Paine, were, if not unique, enduring, and many have thought that he suffered more for this cause than any other Englishman of the nineteenth century. He was imprisoned more than nine years for publishing his republican-political and deistic-religious opinions. Persecution by the ultraconservative government, however, helped make him; he threw upon it. Bentham befriended him, even as Place counseled him. His spirit remained to the last unbroken. Chief among the dozen journals he edited are the *Republican* (1819-26) and the *Lion* (1828-29).

H., *The Struggle for the Freedom of the Press, 1810-1832* (London 1928); Himes, Norman E., "The Place of John Stuart Mill and of Robert Owen in the History of English Neo-Malthusianism" in *Quarterly Journal of Economics*, vol. xlii (1927-28) 627-40, and "John Stuart Mill's Attitude Toward Neo-Malthusianism" in *Economic Journal*, Economic History Supplement, no. 4 (1929) 457-84; and notes by N. E. Himes in his edition of Francis Place's *Illustrations and Proofs of the Principle of Population* (London 1930).

CARLYLE, THOMAS (1795-1881), Scottish historian and critic of society. Carlyle was not in the scientific sense a political theorist or a sociologist. His chief gift, a capacity for moral indignation, is perhaps not the best that can be given to the thinker. In fact, he pretty completely denied the value of the instrument of thought in social questions, affirming instead the force of personality. On the other hand he was more than a preacher and a moralist. Most of his writing was an attempt to shake his fellows out of their unawareness, or their acceptance, of misery. Because he loathed the disorder and suffering which accompanied the industrial revolution Carlyle was accepted, in part, by the new generation of liberals, such as John Morley,

that grew up in the second half of the century. He influenced Ruskin and the two combined to influence intellectuals of both political extremes, a Shaw and a George Wyndham, for example.

Carlyle as historian was vivid, usually accurate, preeminently dramatic and biographical in his method. *Oliver Cromwell's Letters and Speeches* (4 vols., 1845) effected a rehabilitation of the Protector in the eyes of his countrymen. *The History of Frederick the Great* (6 vols., 1858-65) is detailed, accurate, documented, very prejudiced in favor of Frederick, almost silent on his civil achievements, extremely good on military history. But the *French Revolution* (1837) is a classic. It is a grand metaphysical drama which works itself out in a hundred exciting episodes. Moreover, it is historically accurate in detail, as Carlyle made critical use of the sources available at the time. Yet no modern historian will accept it as an adequate account for it wholly neglects economic and social history, simplifies the issues involved and is based on a metaphysics no longer in fashion. It has had an enormous influence on lay readers in English speaking countries and is largely responsible for the commonly held view of the French Revolution as a violent uprising of an oppressed people, a cataclysmic social revolution quite unlike anything else in European history.

Carlyle's enthusiasm for Germany did much to spread the Teutonism so popular in Victorian England, just as his sympathy for the romantic philosophy of the Germans was a vital influence in his own thinking. In his eyes the Teutonic races are virtuous, protestant and inspired by a moral intuition above mere reason (*Life of Friedrich Schiller*, 1825; many translations from the German; essays and pamphlets on German culture). The Latin races are corrupt, worldly, selfish and addicted to barren logic. To follow them is to fall into utilitarianism, orthodox economics and the industrial revolution. Modern England is overemphasizing the importance of the common man, denying the superrational value of custom and tradition, and approaching democracy. This process had already brought widespread suffering to the poor and a cramped spiritual life to the rich (*Chartism*, 1839; *Past and Present*, 1843).

The solution of these difficulties Carlyle felt to be a reversion to the rule of the best, to benevolent despotism. The common man, left to himself, is ignorant and weak. He must at times be kept in his place by force. Carlyle ends

by identifying the forces of might and right (*Latter-Day Pamphlets*, 1850; *Shooting Niagara*, 1867) or, according to his enemies, by accepting the doctrine that might makes right.

CARMIGNANI, GIOVANNI (1768-1847), Italian penologist. In 1791 he received the degree of doctor of legal science from the University of Pisa and after a few years of literary activity inspired largely by Alfieri took up the practise of law. He established a reputation as jurist by the publication of *Saggio sulla teoria delle leggi civili* (Florence 1794) and *Saggio di giurisprudenza criminale* (Florence 1795) and was appointed professor of penal law at Pisa in 1801. This chair he occupied until 1840, when he became professor of legal philosophy at the same institution.

Together with his disciple Francesco Carrara, Carmignani gave to the traditional penological theories of the so-called classical school initiated by Beccaria the final form in which they were to be attacked by Lombroso. The justification of criminal law could be deduced immediately from primordial natural law, according to which every individual is endowed with the right of self-defense. The state assumes the guardianship of these rights and becomes the executor of natural law. In imposing penalties for crime its purpose is not revenge but the prevention of future aggressions against its members. The essential problem of the penologist, therefore, is to determine the exact nature and degree of punishment or rather of "moral coercion" necessary to deter one individual from violating the rights of another. These ideas Carmignani developed in his two principal works, *Elementi del diritto criminale* (Florence 1808; ed. by Caruana Dingli, 2 vols., Malta 1847-48; and by Filippo Ambrosoli, 2nd ed. Milan 1882) and *Teoria*

delle leggi della sicurezza sociale (4 vols., Pisa 1831-32). Although in his early years he favored capital punishment he later became a zealous advocate of its abolition; his mature views on the subject were set forth in *Una lezione accademica sulla pena di morte* (Pisa 1836).

CARNEGIE, ANDREW (1835-1919), American industrialist and philanthropist. Born in Scotland, he came to the United States with his parents in 1848. His duties as private secretary to Thomas A. Scott of the Pennsylvania Railroad permitted him to make personal and business contacts which served him well both at the time and later when he ventured into the iron industry. After his retirement from the railroad in 1865 he combined enterprises in railroad financing and oil with his growing interests in the iron industry. The Pennsylvania Railroad was for a time one of the best customers of his bridge construction company and a party to rebating arrangements with him. By the early seventies he had devoted himself exclusively to the successive partnerships which eventually became the Carnegie Steel Company, dominant in its field. In 1901 he sold the company to the United States Steel Corporation for \$447,000,000.

Carnegie was never a practical "ironmaster." His objections delayed for several years the entrance of his concern into the steel industry. Once convinced of the value of a process, however, he backed it to the full and did not hesitate to scrap existing equipment. He ran his plants to capacity and made extensions and improvements during depressions in order to be prepared for prosperity. A rugged individualist, believing in unlimited competition and the survival of the fittest, he frowned upon combination or amalgamation proposals which involved absorbing plants without regard to their industrial value. He attributed his success to his talent for organization and to his ability to hire men "cleverer than himself" and to hold their loyalty by giving them wide scope for activity and liberal rewards. To his workers he paid only the market price. He had no sympathy with labor organizations, and gave at least passive acquiescence to the militant anti-union policy which characterized his industry.

Carnegie retired with over a quarter of a

billion dollars, and set about putting into practise his conception of the obligation of wealth. He believed that all men of wealth, after having provided a competence for their families, should consider their surplus wealth as a trust fund to be administered in the interest of humanity. Accordingly he gave away a total of \$288,000,000 within the United States and \$62,000,000 in Great Britain. His contributions to libraries and educational agencies reflect his own early efforts to obtain an education; and his donations to further world peace continued an interest evidenced earlier in life.

CARNOT, LAZARE NICOLAS MAR-GUERITE (1753-1823), French statesman and military engineer. Carnot, the son of a notary, was born at Nolay. He was a member of the Legislative Assembly (1791-92) and of the Convention (1792-93), and was named to the Committee of Public Safety on August 14, 1793. While his colleagues regulated munitions, food and propaganda Carnot organized the army. The *levée en masse* drafted by Carnot and Barère and enacted on August 23, 1793, was the first attempt in modern history to mobilize all the available man power and resources of a nation for war. By means of so-called deputies on mission to the army, summary demotions, frequent executions of commanders and rapid promotions of young officers Carnot created an intensely national and republican force under a centralized command. He was the most active member of the committee, responsible for most of the terrorist measures that suppressed insurrection and converted retreat on four fronts into victorious advance. When success was assured and reaction against the committee set in Carnot was saved from trial as a terrorist only by

the cry that he was the organizer of victory. As one of the five members of the Directorate (1795-97) Carnot again managed military affairs and was partly responsible for appointing Bonaparte to command in Italy. After an interval of exile he became minister of war (1800) and member of the Tribunal (1802-07). In 1814 he commanded at Antwerp, surrendering only after Napoleon's abdication. Having served as minister of the interior during the Hundred Days he was exiled by the Bourbons and died at Magdeburg.

CARPENTER, MARY (1807-77), English social reformer. At the age of twenty-six she was profoundly influenced by two visitors in her parental home—Rammohun Roy, a great Indian who gave her a lifelong interest in his country, and Dr. Joseph Tuckerman, who was distinguished for philanthropic work in Boston. Her attention was directed to the needs of the poor and in 1835 she formed in Bristol the Working and Visiting Society, whose activities were in many respects similar to case work. In 1846 she founded a "ragged school" in Bristol, but she soon became convinced of the inadequacy of such schools to meet the needs of the young criminal class. Accordingly she suggested the need of reformatory schools for children who had become habitual thieves and beggars, at the same time urging state aid for ragged schools. She recommended free day schools, "industrial feeding schools" with compulsory attendance and correctional and reformatory schools to take the children out of the prisons. In 1852 she founded Kingswood School and in 1854 Red Lodge (both near Bristol) for juvenile offenders. She was also influential in securing the passage in Parliament of the Youthful Offenders Act of 1854, legalizing reformatory schools, and the Industrial Schools Act of 1857.

Her interest in the education of the women of India led her to visit that country in 1866 and again in 1868, 1869 and 1875. In 1870 she founded in Bristol the National Indian Association to promote a better understanding between the Indians and the English. Before her death many of her plans for social reform in India were put into practise. Her projects for prison

reform received further impetus from her attendance at a congress in Darmstadt in 1872 and from a visit to the United States and Canada in 1873.

Mary Carpenter's work was done in a period of great destitution, vagrancy and criminality. Her achievements in educational and penal reform were the more remarkable in view of the contemporary lassitude toward social abuses. She was a woman with a vigorous and constructive mind and possessed administrative and organizing capacity unusual at a time when the sphere of women was conventionally narrow and limited.

CARPETBAGGERS. *See* RECONSTRUCTION.

CARPZOV, BENEDIKT (1595-1666), German jurist. He was the most noted member of a learned family which included nine jurists and five theologians. For forty years Carpzov was a member of the Leipsic Schöffensteinstuhl, whose decisions at that time made it the most highly regarded court in Germany. It combined the faithful observance of the customary law of Saxony with a vigorous development of the received Roman law and independent quasi-legislative pronouncements. Carpzov integrated all these elements so thoroughly and clearly that his works may be said to be the culmination of the centuries of the reception and to lay the foundation for the jurisprudence of the next century. His authority is comparable to that of Bartolus.

Carpzov's work lay chiefly in criminal law and criminal procedure, and he is regarded as the father of German criminalists. His *Practica nova imperialis saxonica rerum criminalium* (3 vols., Wittenberg 1635; reprinted Basel 1751 and Frankfurt 1758) was the first systematic treatment of German criminal law and enjoyed virtually the authority of law. He drew not only

on Roman and canonical doctrine but also on the *Sachsenspiegel*, on the Saxon constitutions and on the *Constitutio criminalis carolina*, which first attained through him its full recognition in Germany. Because of the 20,000 death sentences which he is said to have pronounced Carpzov is regarded as the exponent of a cruel criminal law. Such a reputation is unjust. It must be remembered that Carpzov lived in the stormy period of the 'Thirty Years' War, and that although he believed that punishment should inspire fear and looked upon the Mosaic law as *jus divinum* he nevertheless set himself against arbitrariness, inhumanity and injustice.

His work *Jurisprudentia forensis romano-saxonica* (Frankfort 1638, reprinted Leipsic 1721) borrowed from his own practise and the books of the Leipsic court. He expounded civil procedure, with its admixture of German and Roman elements, in the *Processus juris in foro saxonico* (Jena 1657, 3rd ed. 1667; reprinted Leipsic 1708). When Carpzov became professor at the University of Leipsic he had to lecture also on canonical law, and it was during this period that he wrote his epoch making work, *Jurisprudentia ecclesiastica* (Leipsic 1649, reprinted Leipsic 1721), in which he may be said to have founded the Protestant ecclesiastical law. Carpzov also produced works on feudal and constitutional law as well as a political polemic against Innocent x, *Vindiciae pacificationis Osna-brugensis*, which appeared in 1653, probably in London, under the pseudonym Ludovicus de Montesperato.

CARRANZA, ALONSO (dates of birth and death unknown), Spanish economist and jurist of the early seventeenth century. He wrote *El ajustamiento i proporción de las monedas de oro, plata i cobre* (Madrid 1629), his chief work, to defend and popularize Tomás de Cardona's nostrum for monetary reform. Accepting the mercantilist premise that treasure, peculiarly desir-

able wealth, can be attracted or retained by inflation, Carranza advocated a twenty-five percent debasement of gold and silver money in order to prevent the export of specie, stimulate the languishing production of precious metals in Spain and the Indies, decrease frauds in the royal quint and prevent smuggling of treasure on the galleons. This scheme, considered by government commissions over a period of more than thirty years, may have influenced the twenty-five percent inflation of gold and silver in 1642. Repeated divagations into theology and sacred history rendered Carranza's literary style unattractive, but his extended residence in Seville and intimate contact with Tomás de Cardona, sometime silver master on treasure fleets, enabled him to describe empirically the mechanism through which Mexican and Peruvian specie reached Europe and entered circulation. *De partu naturali et legitimo* (Madrid 1628), a study of the rights of natural and legitimate children, which is Carranza's best known treatise on law and which passed through numerous editions in Spain and abroad, exemplifies the influence of Roman law on Spanish jurisprudence in the seventeenth century.

CARRANZA, VENUSTIANO (1859-1920), Mexican statesman. Carranza was born in Cuatro Ciénegas, Coahuila, Mexico. After serving some years as senator, in which office he was a member of the group always readily responsive to the will of Porfirio Díaz, the dictator, Carranza was elected governor of his state in 1910. When he was unseated he joined the rebellion of Francisco I. Madero against Díaz. In 1911 he became secretary of war in Madero's cabinet but relinquished this office to finish out his term as governor. When Victoriano Huerta, Madero's new war minister, seized power Carranza, backed by the Coahuila legislature, announced on February 19, 1913, the dissidence of his state. He launched the Plan de Guadalupe, rejecting Huerta, and became the first chief of the constitutionalist army, charged with executive power. After Huerta was overthrown Francisco (Pancho) Villa, heading the "Convention-

alists," and Emiliano Zapata disavowed Carranza and the Constitutionalists, precipitating civil war anew. Carranza, driven out of Mexico City, set up his provisional government in Vera Cruz. These unsettled conditions aroused the concern of President Wilson and resulted in several pan-American conferences, out of which came the recognition of Carranza as de facto president on October 19, 1915, by nine American countries, including the United States. He was elected president on March 11, 1917, and served until May, 1920, when he was driven from the capital by the "revindicating revolution" of Alvaro Obregón and assassinated in the Indian town of Tlaxcalantongo, Puebla, supposedly by rebel troops under General Herrero, an ex-bandit.

From 1915 to 1920 two outstanding concerns dominated Carranza's policy: the necessity of establishing constitutional order and peace; and the problem of relations with the United States, which were complicated by petroleum interests and resulted in the Tampico incident and the consequent American occupation of Vera Cruz as well as in the Villa Columbus raid and the Pershing Punitive Expedition. In 1916 he called a constitutional convention in Querétaro which, on February 5, 1917, promulgated a new constitution for Mexico. The new document followed the framework of the 1857 constitution of Benito Juárez, retaining the threefold division of powers and a legislative system similar to that of the United States. It represented a further thrust at the power of the Roman Catholic church, and aimed at conservation of national resources, regulation of foreign capital, renovation of the judiciary and radical safeguarding of the rights of workers and peasants. Because of Article 27 nationalizing the subsoil it aroused the opposition of American oil companies and provoked danger of American intervention. Antagonism was also aroused between the two countries by Carranza's pro-German neutrality during the World War, by his frequent denunciations of the Monroe Doctrine and by his promulgation of a new doctrine of Latin American solidarity against the United States.

In spite of the corrupt military clique in his government Carranza merits credit for having determined in a coherent manner the outlines, purposes and powers of the revolutionary movement which began with Madero and culminated in Calles. He shaped the constitutional and legal framework on which present day Mexico rests.

History (New York 1923) p. 411-55; Beals, C., *Mexico: An Interpretation* (New York 1923); Gruening, E., *Mexico and its Heritage* (New York 1928).

CARRARA, FRANCESCO (1805-88), Italian penologist. In 1859, after a life dedicated to scholarship and the practise of law, he was appointed professor of penal law in the University of Pisa. Carrara took no part in the movement for the unification of Italy, although after its realization he served as deputy in parliament through two sessions and in 1876 was nominated senator. He was active in the preparation of the project for a unified penal code, which became law in 1889.

In penology Carrara holds an important place in the series of distinguished Italian legal philosophers—Beccaria, Pagano, Romagnosi, Filangieri, Pellegrino Rossi and Carmignani—who through two centuries reconstructed the science of penal law and induced the government to abolish all vestiges of barbarous punishments. He was a disciple of Carmignani but developed the ideas of his master in a direction that excluded all foreign influence. According to Carrara penal law is derived from primordial natural law. It is immutable, being the will of God. Man is endowed with the right of self-defense. If he violates the rights of others, he exposes himself to punishment by the state as guardian of individual rights. State action in defense of individual rights should operate principally through moral coercion, that is, through the threat of punishment, and only as a last resort through the actual infliction of punishment. Carrara was a convinced but philosophical advocate of the abolition of capital punishment. It is in part due to the influence of Carrara that the ideas of Lombroso, as developed by Ferri, never made serious headway in Italy.

CARTEL. The term cartel designates an association based upon a contractual agreement between enterprises in the same field of business which, while retaining their legal independence,

associate themselves with a view to exerting a monopolistic influence on the market. The only part of this definition to which anyone may take exception is the assumption that the tendency of the cartel is monopolistic. Any such exception rests, however, on political not on scientific grounds. Unquestionably the treatment of the cartel in any system of economic theory must be connected directly with the treatment of monopoly (*q.v.*).

Monopoly as relevant to the discussion of cartels is a condition in which a majority of the buyers have to deal with an organized group of sellers. Many prefer to describe the activity of the cartel as a regulation of the market rather than as the exertion of monopolistic influence. But this is merely a vague rendering of the same idea. As a rule a cartel comes into existence only when the greater number of the undertakings which were formerly competing become associated in it. Cartels are collective monopolies of entrepreneurs in their capacity as sellers. Monopolistic organizations of consumers, such as organizations for collective buying, should not be designated as cartels, because their effects are quite different from those of associations of sellers. For the same reason employers' associations, in which the members combine as against the organizations of employees, should be distinguished from cartels.

The cartel must not be confused with the corner or the ring. A corner involves the buying up of a commodity in the market with a view to forcing up the price. It is monopolistic in its operation and may be launched by a single individual. A ring is the association of several individuals for the purpose of carrying out a corner. The difference between the ring and the cartel consists in the fact that the former is not an organization made up of the majority of those engaged in a certain industry or trade, but an association of persons, frequently standing outside of the industry or trade, who through speculative buying may create an artificial shortage and thus profit from selling at the resulting higher prices. A ring is a speculative association, not a union of independent enterprises.

In the sense in which it is used here the term cartel, which is derived from *charta*, a contract, first became current in the late seventies in Germany. It has been established, however, that similar organizations existed in England as early as the end of the eighteenth century, in the coal industry, and also in Ger-

many and France during the first part of the nineteenth century. In the Middle Ages there existed in various industries not controlled by the guilds and also in certain branches of trade monopolistic organizations which did not differ in form from the cartel.

In general, only associations of the larger independent enterprises are designated as cartels. But agreements in the field of small scale industry and retail trade are of essentially the same character, and a monopolistic tendency characterizes the trade unions as well as some organizations of the so-called liberal professions. The concept, "cartel," refers not so much to a particular form of organization as to a definite group of economic persons who operate with a large capital. The risks to capital play a major part in the development of cartels.

The cartel is not, however, a form of capital organization. It is, to be sure, a manifestation of the modern movement toward concentration but not of consolidation of capital. In this respect it differs from trusts (*q.v.*). Cartels are not business undertakings in themselves even when they are closely organized for collective selling through a special agency. In this form of organization the cartels present the character of a sales cooperative with a monopolistic purpose, but apart from this they are no more than contractual associations, which need not assume any external form whatever. For this reason the legal character of the cartel agreement may vary widely. The cartel differs from the ordinary trade associations (*q.v.*) by the fact that its members are obligated to a particular action or omission, with a view to the common purpose of regulating the entire industry. (In German this difference is expressed by the word *Verbände* as contrasted with *Verein*.) The two forms of association frequently overlap; both may be formed within the same membership, and particularly in Germany those trade associations whose original purpose was the general advancement of their trade often furnished the basis for the organization of cartels.

Cartels may be divided into three basic types according to the methods by which they exert their influence upon the market. There are cartels whose direct object is price fixing, cartels which aim at limitation of production or supply, cartels which operate through division of territory. Those of the first type, which may be called price cartels, fix by agreement either definite uniform prices or minimum prices, thus

eliminating price cutting. In cartels of the second type, which may be called production cartels, restriction of output is jointly agreed upon in order to place supply in a favorable relation to demand. Production cartels are organized especially in time of business recession, when prices are depressed by overproduction. They are often a preliminary step toward the organization of price cartels, because price agreements, particularly agreements for increase in prices, are usually possible only when preceded by restriction of output. It is sometimes agreed that the several parties composing the production cartel shall close down their plant for a definite period or operate it at a fraction of its full capacity. In recent times, following the precedent of the American trusts, cartels sometimes dismantle the plants of the members who operate at the greatest disadvantage and compensate the owners through contributions from the remaining members. Sometimes an establishment is bought by a cartel for the purpose of dismantling it. The cartels operating through division of territory assign definite markets exclusively to certain of their members. This would make a complete monopoly possible if every member could be assigned a definite territory. As a rule the cartel assigns territory to groups of its members, not to individual members. There are a number of territorial cartel agreements with enterprises in foreign countries for the delimitation of markets and spheres of interest. The international shipping cartels bear this character in part, but they are in the main price cartels.

These three types of cartels are to be found in a higher stage of development in the so-called *Kontingentierung* or quota cartels. In these the total supply of a commodity may be fixed and each member allotted a definite production quota. More frequently all orders are referred to one selling agency, called a syndicate, which distributes them among the members of the cartel by percentages fixed in advance. Or, finally, the profits may be pooled and divided among the membership in definite proportions. In this case a common understanding regarding prices is not necessary because it is not to the interest of any member to extend its sales at the expense of other members, since it receives only a predetermined share of the aggregate profits. The last two types of cartels are sometimes merged. The selling syndicate takes the product of the members, sells it and distributes the profits as agreed on in advance. In general it may be said

that these profit sharing cartels are a later development and do not appear in all industries, as, for example, in many of the branches of the textile industry. They do, however, play an important role in the iron industry. In addition to these specific cartels there is still another form of industrial organization which is closely related to them but which in itself does not aim at a monopolistic status for its members: associations for dealing with terms of payment, discounts, cost of packing and the like. Such items, if not determined by common understanding, might easily make price agreements illusory. Associations of this nature have been of great importance, especially in the textile industry, in connection with price and production cartels. Apart from their relation to the cartels these associations are very useful to their membership and are very numerous both in trade and in industry.

Germany is considered the classic land of the cartel; it is in Germany that the movement has attained its greatest development. This may be explained partly by the fact that the German law is more favorable to cartels than that of other countries, especially England and America, and partly by the fact that business in Germany had not grown away from governmental control and organization to any such extent as in the western countries. Moreover, there has long been in Germany a strong tendency toward mutual organization. Capitalistic development was by no means so rapid as in America nor had corporate undertakings come to play so prominent a part in the national economic life. The majority of German enterprises is still in the hands of individual owners and the establishment of modest size the prevailing type. The political and social contrasts between the several states of Germany are still very marked, and the German Empire is too large and too varied in its economic development to admit of the development in most industries of nation wide unified enterprises like the trusts. For this reason large undertakings have developed only in special industries. In spite of the fact that financial concentration has made marked progress the importance of the cartel has in no way been diminished.

There are some industries in which conditions are unfavorable to the development of cartels. This is true of agriculture, where cartels play a minor role. In this industry the economic units are too numerous, the variety of products too great, differences in qualities of products

too marked, changes in the quantity and quality of the harvests too pronounced, to admit of a collective control of production or prices. Industries in which qualitative differences, unique models and patterns play a large role, and in which the reputation of the individual firm is an important factor, as well as industries which cater to demand created in large part by fashion, are not well adapted to the operations of the cartel. On the other hand, industries in which differences in quality are unimportant and mass production prevails, such as the pig iron industry and certain other branches of the metal industry, the stone and clay, chemical and paper industries, figure prominently in the history of successful cartels.

The first epoch of cartel formation opened with the great crisis at the beginning of the seventies. The early cartels were justly described as the children of need but it was soon recognized that these associations might prove beneficial to their members in prosperous times as well, since they offered a means for exploiting favorable opportunities to the full. Good times have since been quite as conducive to the formation of cartels as times of depression.

The protective tariff played an extremely important part in the development of the cartel, through restricting foreign competition in certain industries. But a protective tariff is not a prerequisite to the development of cartels. International cartels are possible independently of the tariff system.

After the World War and during the period of inflation the importance of cartels in Germany declined for a time because of the necessity for financial union through mergers and concerns. But this tendency toward union rarely attained the point of monopolistic fusion or trust. The I. G. Farbenindustrie might be looked upon as an exception. Usually an industry remained under the divided control of a number of important concerns which continued to regulate their interrelations through cartels; this was true even in the iron industry. A similar situation appeared in other countries.

In general, cartels are not very permanent organizations. Often they overreach themselves in raising prices and thus give an impetus to new competition. In consequence they are undersold and may be forced to dissolve. When overproduction becomes serious and prices fall sharply, some of the entrepreneurs give up the attempt to continue production at a loss, while others form a new association designed to im-

prove their condition through agreements controlling production and price.

In the last two decades before the war there was in many branches of business a distinct tendency toward firmly organized cartels of greater permanence. Certain of these cartels, often called syndicates, found it more desirable to maintain prices that were fairly stable compared with the fluctuations formerly prevailing. In periods of depression they lowered prices only slightly and kept them from rising too rapidly in flush times. This stabilization of prices represents the most favorable influence of the cartels upon the general economic position.

As a result of their experience with cartels business men have come to recognize more and more clearly that it is more advantageous for them to keep prices as stable as possible than to exploit their monopolistic position to the limit. There will of course always be an element within a cartel which has no sense of moderation and insists on the highest possible prices. But the policy of fixing extortionate prices is mimical to the industry as well as to society at large. In times of marked fluctuation of prices such considerations may lose their force and there is a danger that the cartel organization may be used to obtain the highest possible profits for the members. The remedy for this evil lies in appropriate legislation. It must be borne in mind that it is not only the large scale industries which can make use of the cartel as an instrument for securing monopoly profits. Associations of small local businesses and sometimes even of agriculturists may form price agreements that are quite as injurious to the ultimate consumer.

The cartels call for certain sacrifices on the part of their members—above all, restrictions upon their independence of action. The members are bound by their agreements, which at times involve extensive interference in their private management; they must submit to measures of control which frequently affect the most intimate relations of the business; and in the case of the firmly organized cartel the members often have to transfer a considerable part of their business activity, particularly the business of selling, to the syndicate.

It is frequently the largest enterprises which out of a sense of self-sufficiency do not wish to join the cartels. When the stronger businesses in an industry remain aloof the cartel can have no stability. On the other hand, it is sometimes these very groups that take the initiative in

cartel formation, while the numerous smaller businesses, some of which may represent special interests, are brought into line with much difficulty.

On the whole, the cartels are conservative and operate to protect their weaker members. As competition increases in intensity, capitalistic concentration and the elimination of the smaller enterprises would, as the socialistic formula assumes, proceed more rapidly if the cartels did not exert their conservative influence.

Yet it cannot be said that the cartels have checked economic progress or that they have served merely to secure for existing businesses as high profits as possible. The charge that they have hindered technical progress is not borne out by experience. It remains to the interest of every member of a cartel to introduce technical improvements and to reduce costs. The cartels have sometimes given an impetus to technical progress through making available to their entire membership inventions that would otherwise have been monopolized by a single business. Particularly in countries, such as post-war Germany, that suffer from a shortage of capital the too rapid application of technical improvements involving increased investment is not desirable. That cartels are not an obstacle to progress toward new and higher types of organization, but merely reduce the hardships of the transition period, is proved by the fact that there has been a marked tendency under the influence of the cartel toward the formation of more integrated types of organization such as combines and consolidations.

The cartels are not directed against labor. For dealing with labor the members of the cartels avail themselves of the services of the employers' associations. The cartel is often beneficial to labor because it helps the employers to meet demands for higher wages by raising prices and thus shifting the cost to the consumer. Thus it is conceivable that where cartels exist the struggle between employers and employees may diminish in intensity.

The chief menace to economic society from the cartels lies in the possibility of their making full use of the monopoly position they seek to establish. If their customers, either in industries which take their products for further manufacture, or in trade, are themselves organized in cartels it is possible to pass on to the ultimate consumer the pressure accumulated all the way from the producer of raw material. Since it is the ultimate consumers who find the greatest

difficulty in organizing, they run the greatest risk of becoming the victims of the process. The most effective means for meeting this situation is the purchasing association, which in the future will no doubt play an important part in connection with this problem. These associations may be organized by producers who take the products of cartels for further manufacture or by the ultimate consumers under the form of cooperatives. The organization of such associations should be encouraged. Further direct state intervention in the matter of prices is also necessary under certain conditions.

The activities of the cartel are not, however, an unmixed evil from the customer's point of view. It is to the great advantage of all customers that through cartel price regulation they are placed on an equal footing. No one can secure raw materials or finished products at a lower price than his competitors. In so far as the cartels succeed in bringing about greater stability in prices the customer finds it simpler to make his calculations and his business position is consequently more secure.

The effects of cartels upon the several types of customers vary widely. The middleman or trader has probably been most affected by the cartels that control production. Among the most striking effects of the organization of cartels are the changes that have been wrought in the structure of trade. In general the cartels that are firmly organized as syndicates have exhibited the greatest capacity for reducing trade to a condition of dependence; in some cases they have even partially eliminated the wholesaler. In other cases they have confined direct sales to a small body of wholesalers, reducing the others to a position of dependence upon this small body.

Until the war the effect of the organization of producers' cartels was, on the whole, to weaken the position of trade. Before the cartels appeared trade had often pitted the isolated producer against his competitors; it had often derived greater advantage from rising prices in time of prosperity but it also carried some of the producers' risk in time of depression. Since the war the balance of power between the producers' cartels and trade has shifted more and more to the side of trade. The most mobile elements in economic life, trade and speculation, are the chief gainers from marked price fluctuation. The profits realized in post-war trade enabled the large wholesale trading enterprises to penetrate deeply into the field of production.

There are great industrial concerns which have grown out of the activities of mercantile firms.

The successful operation of cartels in industry has given a great impetus to the formation of cartels in trade. They were first organized with the purpose of passing on to others the pressure imposed upon them by the industrial cartels. Traders have also organized purchasing associations in order to meet the pressure of the cartels, and not infrequently groups of traders or of producers of finished products have set up industrial establishments to supply themselves with the goods they require, thus making themselves independent of the cartels.

It is a characteristic of modern economic life that those engaged in the various fields of economic endeavor no longer face one another as isolated individuals but as members of organized groups of many types and forms. While it is true that this may sharpen economic conflicts it also makes it more possible to establish understandings between different groups. There can be no doubt that the further development of the existing economic system is closely bound up with the tendencies manifested in these multiform organizations.

Most cartels have a natural territory in which, up to certain price limits, they are protected against outside competition by their advantage in transportation costs. Outside of this territory, where they have to meet the competition of other producers, they have to sell at lower prices. In the case of nation wide cartels the internal market is often secure against competition within a certain price level determined by the rate of protective duties. Outside of the protected national market the lower prices of the world market prevail.

Cut price sales in foreign markets, or dumping (*q.v.*), have led to violent attacks on the cartels by those who take the point of view of the national consumer. It is charged that the national wealth is being wasted on the foreigner. But it is worth noting that neither are these low export prices popular in foreign countries, with whose industries they seriously compete. To the charge that dumping represents a waste of national wealth it may be replied that goods are exported at low prices only to keep the wheels of industry going and to provide employment for the workers. It is not a regular business practise; it appears as a rule only during periods of domestic depression and therefore cannot serve as a reliable basis for the building up of foreign industries using such

goods as materials for further manufacture. From a national point of view much depends on the kind of goods which are dumped abroad. Serious problems are presented by the dumping of raw materials. The artificially cheap material places the foreign manufacturer in a strong competitive position and makes it difficult for the domestic manufacturer to compete in the world market.

A closer examination of the case reveals that what places the domestic manufacturer at a disadvantage in the world market is not so much the low prices fixed by the cartel on foreign sales of raw material as the high prices on domestic sales. If a cartel puts prices of raw material at a high level the manufacturer cannot sell abroad in competition with manufacturers enjoying cheaper material, even if the cartel does not export at all. If foreign countries should engage in dumping materials, the home manufacturer might avail himself of the low prices to produce at artificially low costs and to compete in the world market.

A comprehensive policy of dumping is quite irrational. It excites retaliatory measures on the part of foreign countries, such as countervailing duties and import embargoes, and it introduces into the domestic economic life an element of great uncertainty. Cut price exports, even of raw materials and semi-manufactured goods, are usually disadvantageous to the importing country since it cannot count upon receiving them regularly at such low prices.

Dumping at cut prices is usually associated with protective tariffs because duties serve to keep the exported goods from flowing back or to keep out similar foreign goods. But it is quite possible for dumping to arise under free trade. Transportation costs alone are an obstacle to the back flow of the cut price goods. The waste involved in dumping under these conditions is measured by the cost of transportation.

The monopolistic position of the cartel offers a great incentive to the extension of production. Frequently new enterprises spring up outside of the cartel and underbid it in an effort to capture part of its custom. The cartels employ various means to combat such outside concerns. In part they endeavor to put them out of business by the methods of cut-throat competition, fixing extraordinarily low prices wherever the outside competitors appear. Occasionally attempts are made to buy out these competitors, a measure which can, of course, be applied only to a limited extent.

The principal weapons employed by the cartel to maintain its monopoly position and to suppress competition are the exclusive contract and exclusive trade relations. These contracts and agreements are directed against the outside competitor, but the obligations involved are binding only upon the businesses which supply the cartel with its materials or take its products. Agreements of the same nature may be employed to tie union labor to the cartel. The producer of raw material, the trade union or the purchaser of cartel products is bound by the agreement to do business only with the cartel. These agreements are differentiated as exclusive selling contracts and exclusive buying contracts.

Exclusive contracts are not confined to the cartels. They may also be applied by individual enterprises and by trusts. They are a very common means of protecting a preferential position in the economic struggle. Such agreements are especially effective measures for forcing the outsiders to join the cartel, just as the refusal of union laborers to work with non-union men is an effective means of forcing the latter into the union. Often the mere threat of applying the exclusive contract is sufficient to induce the outsiders to join the cartel. When the exclusive agreement is actually put into effect it may in some circumstances ruin the competitor. In spite of the inclination to pass a severe judgment upon such business practices it must be borne in mind that the outsider who is being crushed out deserves little sympathy. Like the worker who refuses to join the union he remains outside of the organization with the hope of profiting by the higher prices it establishes, while avoiding his share of the cost of maintaining the organization. If all business men pursued a similar plan the regulation of any industry by means of monopolistic associations would be impossible.

While these obligations are directed against outsiders they are binding only upon those who supply material to the cartel or take its products, as the case may be. How far are these buyers or sellers justified in binding themselves to deal only with the cartel and to refrain from dealings with outsiders? Here too it is extremely difficult to lay down a general rule. There is no such thing as a general right of the seller to sell to whomsoever he may wish, nor is there a general right of the buyer to buy where he pleases. But the plan of binding either the seller or the consumer to the cartel can also be carried too

far and may lead to serious restrictions upon economic activity and freedom of enterprise. Nevertheless, it must be remembered that a great organizing force resides in contracts and agreements of this character. This force cannot be dispensed with in economic life. It is, for instance, the basis of the beneficent collective trade agreements by which employers bind themselves to engage only workers belonging to the union, who in turn agree to work only for employers who are faithful to the trade agreement.

International cartels have existed for many decades, particularly in industries in which the number of producers in the several countries is small, or among steamship companies. In consequence of the disruption of interrelated economic areas by arbitrary peace treaties and in consequence of the growing capitalistic interpenetration of the various national economies—a trend which is, however, counteracted by the growing tendency toward national isolation—the international cartels have acquired a greater importance, particularly during the last decade, and may confidently be expected to attain yet greater importance in the future. Parallel with the establishment of international cartels is the development of large international concerns with their numerous foreign branches. These concerns may in their turn unite in international cartels.

It is obvious that international cartels will vary both in aims and in methods of operation. In the case of cartels based on division of territory, which are the most common form of international cartel, every country reserves its own territory to itself. Frequently a third country or a disputed market is definitely assigned to one of the contracting parties. Cartels of this type are essentially independent of national tariff systems. The protective tariff, as we have seen, makes dumping easier; but the international cartel of the division of territory type seeks by means of control of imports and exports to eliminate dumping.

It is more difficult to organize international price agreements. Such agreements are important chiefly in relation to market areas in which the producers of the several countries compete. They are often supplementary to territorial cartels, by which the national territory and additional market areas are assigned to the producers of each country.

The formation of international cartels for the control of output is even more difficult,

particularly when the object is to cut down production. It is hard to determine whether the agreement is being lived up to and it is quite impossible to enforce it. Even agreements as to the division of output are very hard to carry through. Yet this is the nature of the most important international cartel that has been organized, namely the Continental Steel Association, which was formed in September, 1926, and which aimed to regulate relations in the steel industry of western Europe. The apportioning of the steel production among Germany, France, Belgium, Luxemburg and the Saar district involves the payment to the regulating agency of a specific sum for every ton produced within the quota and the payment of a higher sum for every ton of production exceeding the quota. Up to a certain point a country has a claim to compensation for every ton by which it falls short of its quota. Various other international cartels operating in the field of steel manufactures have attached themselves to the Continental Steel Association.

The international sales syndicates have gone even farther. Either all orders or those which are intended for export are apportioned among the membership in accordance with a predetermined quota. This was the character of the great railmakers' cartel of 1904, which broke up during the war but was revived in 1926 under the name of "Erma" (European Rail Makers' Association).

International cartels have reached their highest development in two quite different types of industry: the great raw material and key industries, and the specialized industries made up of a small number of establishments which are deeply interested in the export trade. Of the latter group the most important are the great chemical industry with its innumerable special products and the electrical industry.

In industries of the first group international cartels are usually possible only when the several national industries have already been organized in cartels. In many countries cartels are hardly developed at all and this has been a serious obstacle to the formation of international organizations. Differences in legislation are also partly responsible for the fact that most international cartels are somewhat short lived and unstable enterprises.

In industries of the second group international cartels may be organized directly among individual enterprises, particularly if these are large concerns. In these industries international

associations are frequently formed to regulate the terms on which patents may be used. Agreements concerning patent rights are of course not cartels per se, but ordinarily they carry provisions which affect the licensee's position in the market. Thus they may specify the territory in which the licensee may offer the product for sale or the price policy he is required to follow. Such agreements are the most essential part of the international incandescent lamp cartel, which includes in its membership the greatest producers of the whole world.

The relation of the protective tariff to the international cartel is still a moot question. In some circumstances these associations may render protective tariffs superfluous; but in the main the widespread system of protective tariffs facilitates dumping and thus evokes the formation of international cartels as a means of checking the evil. In the writer's opinion, the chief benefit from the international cartels consists in the limitation or prevention of dumping. The cartels contribute nothing, however, toward a more rational division of labor among different countries. Like the protective tariff they exert a conservative influence in helping to preserve home industries whether or not such industries can be conducted as efficiently and economically in the country in question as in other parts of the world.

The chief danger from the international cartel lies perhaps in the security it gives to the national cartel when the latter seeks to exploit its monopoly position. The only possibility of controlling the action of international cartels lies in the national legislation; to work out an international law regulating cartels is a problem for the distant future.

In England, the United States, France, Austria and many other countries cartels and similar associations are forbidden by law. The agreements on which they rest are void and the obligations undertaken by the membership are not enforceable in law. In Germany these agreements are legally valid. The law dealing with them is concerned chiefly with the prevention of abuses arising out of exclusive contracts when they threaten the ruin of either the members or the outsiders against whom they are directed.

In some countries, however, the establishment of cartels has been occasionally encouraged by the government itself through the formation of certain compulsory cartels. A compulsory cartel was formed in the German potash industry in 1910, and similar cartels were formed in

many branches of industry during the World War. A compulsory cartel was organized by the Italian government in the Sicilian sulphur industry in 1906, and recently such cartels have appeared in many other Italian industries; they have also appeared in Russia, Spain and Rumania.

It is often proposed that a special administrative organ should be created, a bureau or a registry of cartels, to maintain a general supervision of their practices. This is thought necessary because these associations prefer to operate under secret arrangements. No such agency has as yet been created in any European country except Norway. It has been proposed that a particular legal form should be prescribed for all cartels but this reform has nowhere been realized. In several countries, particularly in the United States, there have been extensive public investigations of the problem of cartels and trusts. Similar investigations were conducted in Germany in 1905-06 and again in 1927, and in Austria in 1912.

Special laws on cartels have recently been enacted, particularly in Germany and Norway. By the German act for the prevention of the abuse of economic power of November, 1923, a special cartel court was established under the Reichswirtschaftsgericht, to which appeals may be taken not only by the parties to the cartel contract but also by the government. So far the provisions of the act that have proved to be of chief practical importance are those appearing in Sections 8 and 9. Section 8 provides that "every party to contracts and agreements of the kind designated in Section 1 [cartel agreements] may withdraw without previous notice for valid reason." A valid reason is, according to the act, any unfair restriction upon the economic freedom of action of the party seeking to withdraw, particularly as regards production, sale or price fixing. Section 9 provides that "without the consent of the president of the cartel court no bonds may be forfeited nor may any boycott or similar measure be applied in consequence of violation of the kind of agreements or resolutions designated in Section 1." The decisions of the cartel court as to when a valid reason for notice of immediate withdrawal exists or when a boycott is justified are based mainly on the rule of reason and it is difficult therefore to formulate uniform principles underlying them. Recently the court has freely recommended resort to arbitration in disputes arising out of the practices of the cartels.

The Norwegian cartel law of 1926 dealing with the regulation of restrictions upon competition and the abuse of price fixing envisages particularly measures of inspection. Since 1921 Norway has had a compulsory registration law for cartels, trusts and monopolies, under which 418 cartels, 51 other forms of agreements and 58 large monopolistic concerns have been registered. The law of 1926 created two agencies of regulation, the control bureau and the control council. The control bureau administers the provisions for registration, and all business men whose affairs come under its purview may be required to answer a wide range of inquiries into the character of their business operations. The control council functions essentially in the same way as the German cartel court.

The effectiveness of state regulation must not be overestimated. Some monopolistic combines, particularly those of a local character or small membership, will be able to evade control. In most cases public complaints about the practices of a cartel and proceedings before the cartel court and the control office will probably suffice to prevent abuses on the part of cartels. The state is also in a position to exert pressure upon the cartels through the application of various measures of economic policy, one of the most effective of which is the power to reduce the import duties on raw materials when a cartel raises prices excessively. Another practical measure that would have a similar effect is the reduction of railway rates to encourage the importation of goods competing with the products of the cartel. Reducing the tariff in order to control domestic monopolies is a policy that has been applied chiefly by Canada and New Zealand. On the other hand, increased duties may be employed against foreign monopolies which export at cut prices. Such "dumping duties" have been applied especially in Canada, and also in the United States. It is much more difficult to combat international cartels or concerns, which put up prices in every country. The problem of the control of international cartels has far reaching implications, which have been much discussed in connection with the question of the alleged imperialistic tendencies of the Anglo-Saxon world empire. Still, no such thing as a real world monopoly of the more important commodities exists, and the cartel is probably a form of organization too loose and unstable to be able to create such a monopoly.

Many people are inclined always to see the

idea of socialization in the background of all measures for the regulation of cartels and trusts. The branches of industry in which these organizations play a large role are looked upon as "ripe for socialization." It is urged that they should be taken over by the state. Those who take this position fail as a rule to recognize that these industries, with very few exceptions, are unsuitable for public operation, whether by the state itself or by a special administrative organ operating independently of political control. So long as economic life in general remains organized on the basis of private profit—and the socialists themselves recognize more and more that the profit motive cannot be generally eliminated—it is not possible to withdraw important branches of industry from the field of private enterprise and operate them on principles for which the fundamental basis has never been established. Marx's assumption that the competitive struggle leads of necessity to a growing concentration of enterprises and to the exploitation of the masses by a few surviving great businesses, which would have to be expropriated by the state, has not proved itself valid. Indeed, the tendency of the cartel itself is to prevent the competitive struggle from going to the extreme assumed as inevitable by Marx. And even though concerns and trusts will become increasingly important in the future, the cartels, both national and international, will long retain the position of greatest significance in the world economy.

CARTER, HENRY ROSE (1852-1925), American sanitarian. After completing an engineering course at the University of Virginia in 1873 he studied medicine at the University of Maryland. Following his graduation in 1879 he entered the marine hospital service and by 1915 had reached the grade of assistant surgeon general. The study and prevention of yellow fever and malaria occupied a large part of his career. While detailed at Ship Island quarantine station in the Gulf of Mexico he gained the experience upon which was based his recommendations for the control of maritime quarantine by the central government. He was charged with the control of several epidemics of yellow fever in the southern states and later had charge of the antimalaria campaign in the same section. In 1900 he published a description of the "extrinsic incubation" of yellow fever, which had a profound influence upon the decision of the Reed board to

investigate the possibility of mosquito transmission of the disease. His observations showed that a definite period always elapsed between the first and succeeding cases in a locality. This interval was later shown to be the time necessary for the development of the virus in the body of the Stegomyia. Dr. Carter inaugurated a quarantine system in Cuba in 1899 and from 1905 to 1909 was director of hospitals in the Panama Canal Zone. As a member of the International Health Board he investigated yellow fever in Central and South America in 1916 and acted as sanitary adviser in Peru in 1920-21. At the time of his death he was engaged upon an encyclopaedic history of yellow fever.

JAMES M. PHALEN

Consult: Carter, H. R., "Protecting the United States from Disease" in *Hygiene*, vol. iii (1925) 39, 43, 91-94; *American Journal of Tropical Medicine*, vol. v (1925) 385-88; Gorgas, M. D., and Hendricks, B. J., *William Crawford Gorgas* (Garden City 1924).

CARTER, JAMES COOLIDGE (1827-1905), American jurist. Carter was one of those leaders of the New York bar whose clients' cases are either so desperate or so important that they dare employ no other counsel; but he was unique in the moderation of his fees. His writing proceeded mainly from his successful fight from 1878 to 1887 to keep the ill considered Field Civil Code from adoption in New York. His widely distributed pamphlet, *The Proposed Codification of Our Common Law* (New York 1884), argued that in private law justice is of vastly more import than certainty, and that the situations which will arise are unforeseeable. Hence only case law, laying down rules which are at best provisional and can be revised for new situations, can fill the need. The fixed rules of a codification are of necessity either guesses too wild to be risked or definitely unjust. In *Principles of the Written and the Unwritten Law* (New York 1889) the foundation of the argument shifts from justice to inherent necessity. Principles of "the national standard of justice" do in fact govern private transactions; they are absolute; they cannot be made by human enactment but are growths; they can be discovered only by study from case to case; the judges are the experts in discovery. In *The Ideal and the Actual in the Law* (Philadelphia 1890) the doctrine takes on its most satisfactory form. Only in that essay do "thoughts" of the people appear alongside "universal customs" as the essence or sole effective cause of law; there too is the most suc-

cessful approach to describing the work of judge or legislator when custom is indefinite or conflicting or in process of formation. *Law, Its Origin, Growth and Function* (New York 1907), Carter's best known work, builds rather out of the *Provinces* than out of the later paper and suffers accordingly. While judges and legislators approach creative activity when they "seize on tendencies and convert growing custom into positive rules," they cannot create custom; and their attempts to declare it are experiments, futile and "tyrannous" if the rule declared does not fit. Custom "is—what is more and better than known—felt." In his work Carter thus develops, largely independently, ideas approaching those of Savigny, yet more extreme; Savigny's "expert" speaks for and is *pro tanto* the *Volkgeist*, Carter's expert is one only in knowing what lay custom is. The chief virtue of Carter's position is his insistence on the huge scope of extra-official controls in law and on the limitations set thereby to official action. The chief vice of the positive analysis is oversimplification. Carter deliberately disregards, for example, the whole law of governmental organization and of legal procedure; he overlooks modern administrative regulation. The multifortuity and conflict of subgroup "customs" is hopelessly scanted. The realm of flux in which there is no custom and in which officials really create; even more the realm of tolerance in which official determinations, though they counter existing custom, are carried through; and finally the practical effects of judicial "tyranny"—these are too detailed for the vague vastness of Carter's picture. Negatively, his argument attacks not codification as it is—a fresh and fertile start for case law, which at its best already incorporates existing tendencies—but the utopian ideal of the blinder advocates of codification: a closed system, "certain"—and dead.

CARTER, JAMES GORDON (1795–1849), American educational reformer. Carter's serious education did not begin until he was seventeen years old, when he began to work his way through Groton Academy and later through Harvard College. Immediately upon his graduation from Harvard in 1820 he opened a private

school at Lancaster, Massachusetts. It was the common school, however, which engaged his chief attention both then and throughout the remainder of his active life. As early as 1821, in a series of letters in the *Boston Transcript* collected as *Letters to the Hon. William Prescott, LL.D., on the Free Schools of New England* (Boston 1924), he indicated the direction which his efforts to improve free education were to take, by the formulation of the two principal weaknesses of the system: the lack of scientifically constructed schoolbooks and the incompetence of teachers. According to Carter textbooks should aim to teach inductively, first making appeal to experiences familiar to the pupil or to concrete instances, upon which principle and rules could be built. His remedy for the second weakness was described in his *Essays upon Popular Education, Containing a Particular Examination of the Schools of Massachusetts and an Outline for an Institution for the Education of Teachers* (Boston 1826). As the first strong plea for the establishment of normal schools Carter's *Essays* attracted considerable attention in the educational world, but he was unable to persuade the Massachusetts legislature to support his project. In 1827 he therefore founded at Lancaster, Massachusetts, a private institution for the training of teachers. During his membership in the Massachusetts legislature (1835–39), where he served as chairman of the committee on education, he continued to urge the cause of the common school and in 1837 succeeded in securing the creation of a state board of education. He was deeply disappointed by his failure to secure the secretaryship of the board, which went to Horace Mann, and from that time on he became involved in political and financial transactions which caused his influence to decline. Except for his establishment of the American Institute of Education in 1830 the sphere of his activities had been confined almost entirely to the state of Massachusetts. Nevertheless, the ultimate influence of his propaganda in behalf of free education and of normal schools was nation wide.

CARTIER, GEORGES ÉTIENNE (1814–73), French-Canadian politician, legal reformer and promoter of transportation. Cartier entered the legislature in 1849, where he allied himself with John A. Macdonald, leader of the Upper

Canadian Conservatives, and became premier of the United Province of Canada.

As attorney general for Lower Canada he secured the decentralization of the administration of justice by the establishment of judicial districts with resident judges. His chief legal reform was the codification, largely on the Napoleonic model, of civil law and civil procedure in Lower Canada, effective in 1866. He was an active supporter of the Seigniorial Act of 1854, and in 1859 he secured a large increase in the grant for the redemption of seigniors' rights. He also sponsored measures for the improvement of primary education in Lower Canada.

He promoted the development (and use) of river and canals to secure the Great Lakes commerce for the St. Lawrence route, and as chairman of the railway committee of the legislature from 1852-67 and attorney for the Grand Trunk Railway he secured favorable legislation and governmental financial aid for that road, which he deemed essential to national welfare. Later he promoted the construction of the Intercolonial and the early plans for the Canadian Pacific.

Federal union, for which railways were a necessary economic foundation, appealed to him especially as a means of preserving French culture and institutions in Canada. In 1864 he was a party to the coalition which negotiated a scheme of union with the maritime provinces. In defense of local French autonomy he insisted that the new union be federal and carried French Canada with him for "Confederation."

CARTWRIGHT, JOHN (1740-1824), English political reformer. Cartwright, who was brother to Edmund Cartwright, inventor of the power loom, sacrificed a promising naval career by refusing in 1776 to serve against the American colonists, and in 1792 he was deprived of his majority in the Nottinghamshire militia for his liberal opinions. His doctrine of reform can be traced back to his *American Independence, the Interest and Glory of Great Britain* . . . (London 1774, 2nd ed. 1775), a reprint, with prefatory matter, of letters signed "Constitutio" contributed to Woodfall's *Public Advertiser* on various dates from March 30 to June 6, 1774. He held that a people should determine its own form of government and argued therefore that sovereignty over America was not in the British Par-

liament but in the crown alone, acting through colonial assemblies. He maintained also that the British Parliament, having lost its originally representative character, needed restoration by drastic reforms. His proposals in *Take Your Choice* (London 1776, 2nd ed. 1777), which were repeated with little change of substance in his later writings, such as *The People's Barrier* (London 1780), were in essence those afterwards revived by the Chartists. In his arguments Cartwright followed the historical method. His history is usually wrong, but his conclusions are sensible, for his method saved him from some of the dangers of a doctrinaire temper. He founded, or shared in organizing, many reform societies from the Society for Constitutional Information in 1780 to the Hampden Club in 1811. He was called "the father of reform" and was indefatigable as pamphleteer, organizer and political speaker.

GEORGE STEAD VEITCH

CARTWRIGHT, THOMAS (1535-1603), English Puritan divine. He was the leader of the Puritan party which in the reign of Elizabeth aimed at the Presbyterianization of the English church. Primarily he was a Puritan and not a political philosopher. It was as a defender of the Puritan Presbyterian program against Whitgift that he expounded his views of the relationship between church and state and incidentally disclosed his general political principles. In spite of his disclaimer that he did not deliberately "shoot at" the state his teaching teems with political implications. According to his theory of the two kingdoms church and state are two *societates perfectae*, distinct but interdependent like the Hippocratic twins. Cartwright applied his ideas of sovereignty to the church, but his opponents pointed out their applicability to the state. In the ideal church the mixed sovereignty—democratic, aristocratic and monarchical—is exercised by the members, the office bearers and Christ respectively. Cartwright took the oath of supremacy but on the understanding that Elizabeth's governorship of the church was limited by the absolute sovereignty of God, the headship of Christ and the *jus divinum* of Presbyterianism. He differed from the Calvinistic monarchomachs in Scotland, France and

Holland because he lived in different circumstances. Elizabeth was neither an absolute tyrant nor a Romanist. Her anti-Spanish, anti-Jesuit, anti-Guisian activities were favored by the Puritans. She was not bad enough to make Cartwright and his fellows preach resistance and tyrannicide.

As a Calvinistic reformer, humanist and Englishman Cartwright brought a largely unconscious bias to the interpretation of the Bible, the ostensible source of his views. He was intimately acquainted with Aristotle's *Politics* and many Aristotelian principles are embodied in his teaching. The revival of Aristotelianism which roused the violent opposition of Hobbes, the great protagonist of the unitary state and absolute monarchy, synchronized with the recrudescence of Cartwrightism in the seventeenth century. It is interesting to note the relationship of Cartwright to Melville, the advocate of the two kingdoms theory in Scotland; and to Hooker, whose *Ecclesiastical Polity* was largely a counterblast to Cartwright's position, and also the connection between Cartwright's tenets and the Puritan program during the civil war of the seventeenth century.

CARVALHO E MELLO, SEBASTIANO
JOSÉ DE. *See* POMBAL, MARQUEZ DE.

CARY, JOHN (date of birth unknown—died c. 1720), British economist. Cary was a prominent Bristol merchant whose *Essay on the State of England in Relation to Its Trade, Its Poor and Its Taxes* (Bristol 1695; reissued in 1717 and 1745 under other titles, and in French, 1755, and Italian, 1764) is an excellent summary of contemporary mercantilist opinion. It illustrates in particular the stress placed on employment as a criterion of national prosperity. He held it to be the duty of the state to inquire which trades were advantageous and which disadvantageous to the country, in order that the former might be actively encouraged and the latter discouraged. This obligation was, in fact, placed on the Committee for Trade and Plantations established in 1696. Cary advocated the repeal of customs duties on exported manufactured goods and imported raw materials. He graded raw materials according to the amount of

labor required to convert them into finished manufactures and held that those which would give the greatest employment would add most to the national wealth when reexported as finished products. He estimated the value of the colonies according to the amount of employment in the mother country promoted by trade with them. Holding the conviction that "industrious people are the wealth of a nation" he favored the provision of work for the willing and the use of force on the unwilling. On this principle he agitated for a local act of Parliament to enable Bristol to administer its nineteen parishes as a single area through an elected corporation of the poor. The employment of the able bodied poor was to be organized in a workhouse, where children also were to be trained to be self-supporting. After a few years Cary recognized that the scheme was a financial failure, but it was the model for several local experiments in the eighteenth century. Cary also wrote in favor of protection on manufactured goods, of bullion import and of the establishment of a national bank with provincial branches "on the credit of Parliament" to issue interest bearing notes to depositors and to make loans. In the British Museum (Add. Ms. 5540) there is a volume of his correspondence, part of which is with John Locke, who describes the *Essay* as "the best discourse I ever read on that subject."

J. F. REES

Consult: Macleod, H. D., *A Dictionary of Political Economy* (London 1863) p. 391-93.

CASA DE CONTRATACIÓN was before the nineteenth century the chief administrative agency for the regulation of commerce between Spain and her overseas possessions and the earliest institution created specifically for the governance of the American empire. Founded by royal decree of January 20, 1503, it was in June established at Seville, the mercantile capital of Castile, to whose sovereign the Indies were held to belong. In the beginning the Casa was without doubt planned to be the trading house of the crown, corresponding with royal "factories" in the New World. But this soon proved to be impracticable, and it became a government bureau licensing and supervising all ships and merchants, passengers and goods, passing to and from the Indies, and seeing that the laws and ordinances relating to them were meticulously obeyed.

The Casa received and cared for all gold, silver and precious stones remitted to the crown

from American mines and collected the *avería*, or convoy tax, and customs and other duties. Transcripts were kept of official communications passing through the Casa to America and of correspondence from America about trade and finance, as well as accounts of receipts and expenditures of the colonial treasurers. The officers of the Casa might propose to the king any measure they deemed necessary for the organization and development of American trade. The institution therefore became a sort of ministry of commerce and one of the principal outposts of the royal exchequer.

The personnel of the Casa consisted at first of a treasurer, a comptroller (*contador*) and a factor or business manager, who were expected to meet for consultation and joint action morning and afternoon every day in the year except holidays. With increase in the volume and complexity of business, from time to time subordinate officials, secretaries and legal counselors were added, and the three original officers became executive heads of large departments. In 1514 the office of postmaster general was created, and Philip II added that of president of the Casa. From 1588 there was a purveyor general of armadas and fleets with a staff of his own, and at the close of Philip's reign a Tribunal de la Contaduría, or board of audit. In the seventeenth century appeared a commandant of the navy yard, a staff to superintend the purchase and testing of artillery and powder and to teach gunnery and another to administer the *avería* for the defense of the annual fleets.

A chief pilot was appointed as early as 1508 (the first being Amerigo Vespucci), and under his direction there gradually developed a hydrographic bureau and a school of navigation for the construction and validating of nautical charts and instruments and for teaching and examining pilots for the "India" traffic; a professorship of cosmography was established in 1552. One of the duties of the chief pilot and his associates was to maintain a careful and systematic record of the results of geographical discovery and exploration, and a standard map, *Padrón real*, was kept in the Casa to which all charts had legally to conform.

The Casa was also a court of law. Its officers very early attempted to exercise judicial authority over infractions of its rules and in disputes between merchants and mariners engaged in the American trade. Coming into conflict with the local judiciary of Seville its competence was in 1511 defined by the crown to cover all civil suits

growing out of the trade and the crime of baratry as well. Its three officials were therefore referred to as *jueces oficiales*. Final shape was given to the Casa's jurisdiction by Charles V, who in 1539 granted it exclusive authority not only over infractions of its ordinances but over civil suits affecting the revenues of the crown and over all crimes committed on the voyage to and from America, with appeal in important cases to the Council of the Indies.

A *fiscal*, or prosecuting attorney, was added to the Casa's staff in 1546, and such was the increase of judicial business that in 1583 a separate chamber, or Sala de Justicia, was created consisting of two, and later of three, justices. Thereafter the Casa comprised two quite separate branches, administration and justice, the president serving as the link between them. The erection at Seville in 1543 of a Consulado, or guild of merchants trading with America, had meantime somewhat reduced the number of civil cases. The officers of this guild, a prior and two consuls elected annually by the merchants, took over the settlement of all civil suits between members, including proceedings in bankruptcy. Their methods, simpler and more expeditious than those of the ordinary law courts, relieved the Casa of a great mass of judicial work.

Another subordinate institution was the Juzgado de Indias at Cadiz. As all trade with the New World had to pass through the Casa its control was from the outset restricted to a single port for the whole of Spain. And in spite of the claims of other cities, of protests from the colonists and of efforts of the emperor, Charles V, to overrule the monopoly, for two centuries Seville retained this high privilege. Owing to the difficulties and dangers of the bar at San Lucar—Seville's entrance to the sea—and the shallow channel of the Guadalquivir up to Seville, ships from 1508 on were permitted to lade either at Cadiz or San Lucar under supervision of an inspector from the Casa. In 1535 the crown appointed a permanent resident, *juez oficial*, at Cadiz, and ships and fleets returning from America were frequently allowed to make Cadiz their port, provided cargoes and registers were transported intact to Seville. This institution was throughout the sixteenth and seventeenth centuries a source of perennial jealousy and dispute, since the advantages of Cadiz harbor attracted shipping more and more to it, until a new dynasty in 1717 transferred the Casa entire to the rival port and the Juzgado de Indias was assigned to Seville.

The Casa had charge also of trade with the Canary Islands and with the adjacent African coast. The Canaries were a regular port of call on the outward voyage to America, and early in the reign of Philip II an organization similar to that at Cadiz was set up in the three principal islands.

The Casa de Contratación exercised its greatest influence under the Hapsburgs before the eighteenth century. It was the nerve center of a rigid and elaborate system designed to monopolize all American trade for Spaniards and to secure to Spain all the bullion that came from the New World. The system, adopted by a relatively non-industrial country neither rich nor very populous, proved to be only an instrument of disaster. In spite of minute regulation and supervision, evasion, with or without the connivance of officials, was very prevalent. Great numbers of unlicensed persons slipped out to America, and not only did contraband trade flourish at Seville and Cadiz but foreigners engaged directly in trade with ports in the colonies.

In the eighteenth century, with the economic reforms gradually introduced by the Bourbon kings, the importance of the Casa slowly declined. The Andalusian monopoly was infringed by the creation of privileged trading companies capitalized and operating in the north of Spain, and under Charles III commerce was gradually thrown open between all important Spanish seaports and all parts of the American empire. When the old canalized system of trade was abandoned the Casa had lost its excuse for being, and in 1790 it was abolished.

CASAUX, CHARLES, MARQUIS DE (1728-96), economist. Casaux was born on the island of Grenada in the West Indies and was a sugar cane planter there for many years; the latter part of his life was spent in England and France. He is known primarily for his theory of the automatic self-regulation of society, which he elaborates in his most important work, *Considérations sur quelques parties du mécanisme des sociétés*. The author maintains that "whatever is needed to compensate for the results of an injustice to the public will always be performed through the public." Provided that all obstacles to its operation be removed by the leaders of society and that knowledge of its existence be widely enough diffused, this regulative force will function without further outside intervention. Examining in the light of this theory the contemporary economic situation in England and France Casaux strongly advocates the destruction of monopoly and the introduction of free competition as a means of obtaining the just price. The interests of the three principal classes in the state, the landowner, the industrialist and the capitalist, require a maximum of production and freedom from restraint. A large section of the *Considérations* deals with the problem of the English sinking fund as a means of redeeming the public debt. Anticipating both Hamilton and Ricardo he attacks the sinking fund on the ground that redemption is no longer imperative since the charges of the debt have been rendered relatively insignificant by the vast increase of national income resulting within the last century from such factors as the doubling of wages and trebling of foreign trade. Because of the necessity of effecting a "just equilibrium between agriculture and national industry" taxes on the entire consumption are preferable to a discriminating single tax, whether imposed on land or luxuries. The principle of taxation is justified by the fact that the inevitable rise in prices which results is compensated by an automatic rise in wages. Casaux was also an advocate of internationalism; the conclusion of the Eden Treaty of Commerce in 1786 represented to him the triumph of his ideas of permanent peace based on reciprocity. After leaving England in 1788 Casaux visited France, where during the early years of the revolution he wrote numerous pamphlets—and occasionally advised Mirabeau—on contemporary economic, fiscal and constitutional problems.

STEPHEN BAUER

Important works: Considérations sur quelques parties du

mécanisme des sociétés, 3 vols. (London 1785-88), tr. by Parkyns MacMahon (London 1786); *Questions à examiner avant l'assemblée des États Généraux* (Paris 1788); *Simplicité de l'idée d'une constitution et quelques autres qui s'y rapportent* (Paris 1789); *Absurdité de l'impôt territorial et de plusieurs autres impôts, démontrée par l'exposition des effets ou réactions des différentes espèces de taxes sur tous les prix tant du travail que de ses produits, soit dans l'agriculture, soit dans l'industrie* (Paris 1789).

CASE LAW is law found in decided cases and created by judges in the process of solving particular disputes. Case law in some form and to some extent is found wherever there is law. A mere series of decisions of individual cases does not of course in itself constitute a system of law. But in any judicial system rules of law arise sooner or later out of such decisions of cases, as rules of action arise out of the solution of practical problems, whether or not such formulations are desired, intended or consciously recognized. These generalizations contained in, or built upon, past decisions, when taken as normative for future disputes, create a legal system of precedent. Precedent, however, is operative before it is recognized. Toward its operation drive all those phases of human make up which build habit in the individual and institutions in the group: laziness as to the reworking of a problem once solved; the time and energy saved by routine, especially under any pressure of business; the values of routine as a curb on arbitrariness and as a prop of weakness, inexperience and instability; the social values of predictability; the power of whatever exists to produce expectations and the power of expectations to become normative. The force of precedent in the law is heightened by an additional factor: that curious, almost universal sense of justice which urges that all men are properly to be treated alike in like circumstances. As the social system varies we meet infinite variations as to what men or treatments or circumstances are to be classed as "like"; but the pressure to accept the views of the time and place remains.

The practical universality of case law in some form does not make less significant the great differences in its detail and in its scope within different legal systems. Case law modified by statute is the essence of the Anglo-American judicial system. For the case law is the background against which statutes are viewed; it governs wherever no statute has entered. Indeed, statutes are in the main regarded as innovations on case law, to be limited in their application;

and after their enactment case law provides both the wherewithal to fill gaps in their subject matter and the technique of interpreting what they cover—so much so that it is a legal commonplace that no man knows what a statute means until the courts have "construed" it. The effects of this process are to be traced in two directions. Statutes are, in our system, drawn typically in some haste and none too skilfully; inevitably their words cover more or less than what was intended. The judge with a specific variant before him has an opportunity to fit the statute to changing facts. On the other hand, where the older case law closes the judge's eyes to a statute's purpose it may destroy the main value of legislation: the ability to strike out with relative freedom on new and needed lines.

Legislation works by generalization in advance and with an eye to the future as far as human institutions will allow; case law works deliberately with an eye to the past, adjusting individual variants as they arise. Because of this individualization of decisions case law is grandly unsystematic, grows in isolated, uneven, often inconsistent ways and directions in different areas of the law and shows an ever recurring and ever increasing tendency to assume disordered unmanageable bulk. In all of this it contrasts somewhat with the single statute, but most sharply with the systematic codification of rules of law by statute. For the essence of a code is the attempt to arrange all the relevant law in clear cut authoritative form. An unofficial compilation of case law such as the *Sachsenspiegel* or the pending Restatement of the Law, if it wins unofficial authority, or a partial code such as the Uniform Sales Act more or less approaches the character of a codification in its effect on rigidity of the law.

The relation of code and prior case law has been much discussed, especially on the continent. Primitive codes often represent a political compromise involving reform of the prior case law. Indeed, since case law is uneven and often self-inconsistent all codes represent some reform. Yet a successful code must apparently be built directly or indirectly on case law, the repository of legal experience. Such was the basis of Justinian's code and the famous modern European code; it has also been the basis of the partial codifications of the common law. Less discussed but equally important is the relation of code and post-code case law. Three features of the code are of particular impor-

C. C. Langdell (*q.v.*) in 1871 as a revolt against the older methods of legal education (*q.v.*). Before Langdell, training in law in the United States had been secured partly by the apprentice system, partly in law schools in which the predominant method of instruction was the lecture; or the instructor used the printed lectures of others and quizzed on the texts. The essential features of the case method, on the other hand, were the use of actual "cases," i.e. court opinions, as the main content of the courses of study, and an emphasis on discussion in class.

The case system was based on certain fundamental premises as to the nature of legal science and practise. One was that lawyers in practise must work out what courts will do, and how to argue to them, largely from judicial opinions, and that the law student can best learn this job by doing it. A second premise was that the study of concrete factual situations and of the decisions on the issues raised provides the basis for a discussion class, gives substance and content to the rules concerned and makes for sounder and more interesting teaching. The third underlying premise of the method will not hold water, namely that the determination of legal principle (viewed simultaneously as a means of predicting how cases will come out and as a means of determining "the right" solution) is a "science," like a natural science, and capable of accurate inductive study; and that the basic materials for observation are the opinions of the judges. According to this conception the number of "principles" was relatively small; they were reflected in the cases, and unfolded themselves in the course of history to him who had an eye to discover them. An instructor who had grasped these principles could select in any field of law a series of cases, most commonly arranged by date, in which the principles were reflected, and could lead the student to extract these for himself. Interspersed, to stimulate thought and discussion, would be occasional cases where the judges had gone wrong. In the classroom the accurate statement, the working out and the cross play of principle could be accomplished by putting hypothetical cases. Whatever the validity of these premises, the advantages of the case system as a method of instruction are obvious. Instead of hearing or reading general rules ready made, from some unexamined source of authority, accepting them and then attempting to apply them, the student was to dig out his general rules for himself. In the process, he

would develop an ability to think; he would learn to handle himself in legal argument; he would acquire, even, a degree of skepticism concerning some rules which some men had formulated.

A necessary corollary to the case method, as soon as the class grew large enough to press upon the library, was the casebook, i.e. the separate printing of a selected series of opinions for discussion. The cases in such a compilation are, to be sure, more or less edited; and the more they are cut in the editing, the farther the student is removed from real wrestling with the original sources. This does not, however, remove the advantage of inductive thinking, nor that of dealing with the concrete. Important for the widespread adoption of the case method was the magnificent series of pioneering casebooks produced by James Barr Ames (*q.v.*). But a relic of the older lecture or textbook system is still found in those "casebooks" which, instead of raising problems for discussion, merely string together illustrative cases, in which the language of each rule appears.

Though decried at first, especially as being too difficult, the case system had made its way into all American law schools of the better class by 1915. Now that the struggle over its adoption has died down, certain drawbacks to the system are receiving attention. These disadvantages are partly a result of the increasing size of law classes, which makes the actual dialectic tend to center on a few of the better men, while the class at large becomes an audience. To a greater extent, the difficulties lie in the method itself and in certain excrescences attendant on its general use.

Knowledge of the positive law is won under case discussion only at heavy cost in time. The field of law is vast; the student needs a speaking acquaintance with many matters which there is no time for case discussion to bring out. This calls not for the displacing of the case technique, but for the use of supplementary material. In part, informational footnotes to the casebook fill the need; in part, lectures; in part, outside reading, especially under the pressure of impending bar examinations. More troublesome is the fact that a good student can learn the case technique in a year or so and then ceases to have much use for an instructor. His needs have been met, to some extent, by the law reviews, on which the better students do independent research work as editors. And there is a distinct tendency, by the use of moot courts

or of essay problems, to make training in legal research and argument a part of the course of study.

More vital, however, are the results of the practise of summarizing the cases and decisions for the student. Here the presupposition of the existence of exact legal principle has had far reaching effects. The casebooks have been built up largely in an effort to make clear basic principles, the deductive use of which gives a sure key to prediction and a touchstone to the rightness or wrongness of decisions. Desiring to put the student in secure possession of these principles and to clarify for him fields of law in which no undergraduate can be a specialist, the instructor tends to state the law in orderly fashion, and the student to accept the recurring summaries without much thought. Such summarizing is not inherent in case method teaching; neither is that tendency toward sweeping generalization which marches hand in hand with the search for principle—an emphasis less on the facts of the case in hand than on the rule, and on rules ever wider. But in a number of casebooks this has proceeded to the point of striking the facts from many of the cases, to save space; whereas the one peculiar advantage of the case system lies in the concrete character of the material dealt with. On the other hand, one trend of casebook making at the present time, as at Yale and Columbia, tends to add to the statements of fact in the opinions a considerable body of other information about the layman's practises concerned therein, in order to facilitate both an understanding and an evaluation of the bearing of the case.

Another difficulty in the case system lies in the problem, even when the cases are severely edited, of presenting a sufficiently wide sampling of judicial behavior to lay a foundation for accurate prediction. Experiments to meet this need turn on the assumption that the vital aspect of the case system may prove to be an increased use of summaries of specific situations followed by statements of what the judges have done with them, with less stress laid upon the precise language of the original opinions.

The case system has proved itself an indispensable tool for teaching classes the technique of reading cases, and is unequaled as a means of bringing out the distinction between the actual decision and the passing dictum. It has proved its value also as a tool for teaching comparative analysis. The chief weaknesses of

the method lie in its failure, if unsupplemented, to train the average student in the independent use of the library, or in synthesis which will be on a par with his analysis; and in its failure to deal adequately with that rapidly growing phase of our law, the statutes. Certain statutes, which either rest on case law, such as the uniform commercial acts, or have been very frequently construed, like the Bankruptcy Act, are dealt with effectively enough by the case method; but its net effect is underemphasis of legislative law. Finally, it will be observed that the emphasis of the case method is on teaching what the rules of law are, i.e. the formulae employed by courts in dealing with disputes, and how they may be known when seen. Where the cases are arranged historically it shows also something of what the law has been. It has no necessary concern with how the "rule of law" is to be used by the lawyer in his office (the translation of precepts into action), or with what the rule means to the people it purports to regulate, or with why the rule came to be what it is, or how to build an argument on any but a narrow point. Much case method teaching, therefore, never gets farther than the setting up of the "right" formulae. On the other hand, every one of the matters just mentioned lies close at hand in case method teaching, because of the constant presence of specific states of fact; and every one of them can be made part of the study by any instructor who is so inclined.

The effects of the method on the student's outlook depend wholly on the instructor's point of view. All that the method guarantees is higher skill than is attainable without it, whatever approach to legal matters may be inculcated. All present indications are, however, that the utility of the cases will be increasingly appreciated, and that the case method, in its essence, will stand more firmly than ever at the core of our legal education.

In recent years considerable attention has been attracted by applications of the case method to other fields. Sharply to be distinguished from the case system in law is the practise of social case work. A distinction must also be drawn between the case method in law and the case method as applied to sociology and economics, in that the latter has, up to the present, been largely a research technique rather than an educational device. On the other hand, the case method in medical study approximates that in law, with this distinction: in medicine, as in any social science in which inductive

teaching is attempted, the "cases" presented are observers' descriptions; whereas in law the cases were originally, and still are prevailingly, the courts' own record of their own doings, and thus possess greater authority and at the same time less objectivity.

CASSATION, COURT OF. *See* APPEALS, JUDICIAL; COURTS.

CASSELL, ERNEST JOSEPH (1852-1921), English financier and philanthropist. Cassell was born at Cologne, the son of a Jewish banker. After learning the elements of banking with firms in Cologne, Liverpool and Paris, he obtained a position with the London financial house of Bischoffsheim and Goldschmidt. He became manager at the age of twenty-two and ten years later was made partner in the firm. Although this association continued for many years Cassell carried out a considerable number of his more important enterprises independently. He was regarded as one of the most influential and trustworthy men in the city circle of high finance and as a speculative expert rather than a speculative gambler. He introduced something of the German banker's practise of cooperating with industry, as for example when he undertook the application of the Thomas-Gilchrist smelting process to Swedish mines tapped by the railroad which he had financed, thus creating a profitable mining industry and increased revenues for the railroad. Cassell specialized in the financing of government loans and public utilities. The Swedish Central Railways, the Mexican Central Railway, the Electric Traction

Company (London), the Central London Railway, the Irrigation Investment Company (which built the Nile dams at Assuan and Assiut) were all financed by him. He floated loans for Mexico (1893), China (1895), Uruguay (1896), Morocco (1906) and Turkey (1909). He also played a considerable role in building up the Vickers munitions companies. Many of his ventures were made in consultation with the British Foreign Office and he was given many public honors. In private life his interest in sport, his patronage of the arts, luxurious hospitality, impressive philanthropy and conversion to the Roman Catholic church reflect the common history of numerous brilliant and successful English bankers of German-Jewish extraction. He was one of an interesting company of men who did much to develop English industry at home and English trade and influence abroad.

W. H. DAWSON

CASTE. A caste may be defined as an endogamous and hereditary subdivision of an ethnic unit occupying a position of superior or inferior rank or social esteem in comparison with other such subdivisions. It resembles the clan in being a social unit within a larger political or cultural whole, and in being marriage regulating and therefore hereditary from the point of view of the individual. It differs from the clan in being endogamous, whereas the clan is exogamous and therefore necessarily unilateral as to descent; also in that the castes in their very nature are ranked or rated, whereas clans are essentially equivalent within the society which they constitute. The caste and the clan may be roughly described as horizontal and vertical divisions respectively of a population. Castes, therefore, are a special form of social classes, which in tendency at least are present in every society. Castes differ from social classes, however, in that they have emerged into social consciousness to the point that custom and law attempt their rigid and permanent separation from one another. Social classes are the generic soil from which caste systems have at various times and places independently grown up.

These systems have had an outward or analogous similarity but have often been without historical connection and have thus had no true homologous relation of structure. The similarities between most of the various caste systems of the world are therefore conceptual or psychologically founded, not genetic. It follows that no single factor or stable set of factors is to be

looked for as the universal cause lying at the root of caste. Conquest, race differences, religion, economic developments, all have contributed, and in varying degrees, to the growth of the several caste systems. Nor are the phenomena of caste any more uniform. There are societies, like that of India, which are consciously and unresidually caste organized; in mediaeval Japan and Europe there were others in which caste organization was chiefly at the top or bottom; in modern Europe there are still other societies which are in principle casteless but have had injected into them a few *de facto* castes, such as Jews and gypsies, which remain more or less nonconformable to the general scheme of society.

It is in India that caste has had its completest development. Only there has it become an intricate system which has entwined all aspects of the civilization with which it was able to come into contact. Indian caste accordingly forms the most integrated as well as the most self-conscious system that has grown up anywhere: a pattern stamped on most parts of Indian civilization. In spite of this it seems to be less than three thousand years old. The *Vedas*, of 1000 B.C. and beyond, did not have it in a substantially developed form. By Buddha's time, around the fifth century B.C., it was already fairly prevalent; and the Greeks report it a few centuries later. Whether it is a further development of germs present in the little known native south Indian culture, or the result of clash of Aryan and Dravidian, is not known. According to Hindu theory, four castes were instituted at the beginning of things and are eternal: Brahman, Kshatriya, Vaishya and Shudra, or priests, nobles, cultivators and serfs. This dogma appears never to have been anything more than a scheme representing things as the Brahmins liked to systematize them. The same holds of the native theory that the multiplicity of castes originated from unlawful marriages between the four standard castes; this is merely a piece of ingenious logic. Actually the census of India records over eight hundred castes and subcastes, or nearly five thousand, counting minute or wholly localized ones. These include not only occupational groups but tribes, races, sects, in fact all populational bodies possessing any distinctive traits and group consciousness. The Parsees, fire worshipping Persian refugees, are treated as a caste; so are the Todas and many another primitive hill tribe; so are fishermen, scavengers, jewelers; so, in some districts, are

Christian converts. Even self-sufficient groups whose racial or cultural origin is foreign and who are not intrinsically interested in constituting a caste are forced into the mold by Hindu opinion. And castes are still forming by fission. In two adjacent areas the members of the same caste may be forced by economic circumstances to follow somewhat different trades. If one of these trades should rank a little more honorably, two subcastes arise, one of which begins to look down on the other as a poor relation. As their status in the community moves slightly upward, they become socially proud and discountenance remarriage of widows, which caste custom has heretofore tolerated. The less successful section adheres to its old law, there are recriminations, and two new castes have been established. Again, a part of a group migrating or drifting into a new environment may find its occupation more or less lucrative and highly rated than formerly, and before long a new caste has arisen. Every new cult carries with it the potentiality of a new caste, as does every new conquest made by a population rather than by an army.

It is clear that the history of Indian caste is extremely complex and its causes manifold. Any attempt to explain the system on the basis of a single factor may therefore be attractive to those who like simple formulae, but is foredoomed to partiality and unsoundness. The most persistent of these attempts is the racial explanation of the origin of caste. It is true that one of the Hindu words for caste, *varna*, means color; but we, too, often use "color" in the sense of "kind." It is also true that anthropometric records show on the whole lighter skins and narrower noses for high castes. But the social ranking of the castes and their physical indices do not by any means agree uniformly, even in the same area; in south India, for example, the members of high castes are broader-nosed than those of the low castes in the north. While race consciousness may have given the first impetus to Indian caste, it is at present, and has been for a long time past, a much less potent factor than economic status.

Religion has deeply influenced Hindu caste, especially the old and almost universal tenets of immortality of the individual soul, rebirth according to a scheme of moral causality (*karma*) and earning of merit by restraint and conquest of the passions. Numbers of the higher castes are "twice born" as human beings; in a previous existence they belonged to a low caste. More duty is incumbent upon them because they represent greater merit. Hence they are subject to

innumerable tabus affecting food, sexuality, cleanliness, conduct, from which the contaminated and contaminating lowly castes are exempt. A Brahman may eat only vegetable food prepared by another Brahman and must partake of it without being observed; the lowest castes eat anything, even beef and pork. Varying with her caste, a widow was burned, secluded, grudgingly permitted to remarry or wholly freed. A low caste man may not touch or even approach a Brahman; but he leads in general a far freer life. Worth, in caste as in personal conduct, is therefore spiritually earned and maintained by merit, in Hindu theory and partly in practise.

The Hindu does not feel caste a burden as the individualistic occidental might. To him it seems both natural and desirable, its deliberate breach unnatural, perverse and unforgivable. Whatever his caste, the Hindu is proud of it, as westerners are of their nationality. It gives him a sense of solidarity, and he does not seek to escape it. Of course, caste is as incompatible with full acceptance of the occidental economic system as it is interadapted with the native one. In the contact of the two idea-systems, caste will either be broken down or will keep India economically mediaeval or will hybridize into some new and unforeseeable cultural form.

How far the ancient Mediterranean world developed castes is a matter partly of definition, partly to be determined by further research. Egypt showed certain tendencies in the direction of caste; Mesopotamia seems to have been rather remarkably free from them. The Spartan division of the population into citizens, *πελοποι*, helots and slaves, and the Roman into patricians, plebeians and slaves, merely approached a caste system: they were frankly based on wealth and land holding and, unlike Hindu castes, were of political importance. It is theoretically significant that the Roman system appears to have been founded on economic circumstances, the Spartan on conquest; and that most of Greece followed the latter only slightly or not at all.

During the Middle Ages there developed in Europe a quasi-caste system, with aristocratic rank and privileges, sumptuary laws, feudalism, and occupation guilds in control of much of industry. The classes, however, never crystallized into complete castes, and the final religious sanction was never obtained. In fact the spirit and tendency of the Catholic church were set in the opposite direction. Japan is often cited as a land

of caste; this was true to perhaps the same degree as of mediaeval Europe. Sharp distinctions of hereditary rank, and elaborate formal expression of these, there certainly were; but occupational elaboration and integration with religion remained vague. Chinese society is essentially casteless. Officials, farmers, artisans, merchants, are theoretically ranked in that order, but actually a wealthy merchant outranks anyone but high officials. The absence of both warriors and priests from the scheme is notable. Descendants to the third generation of jailors, actors and prostitutes were ineligible to take examinations for office; but this provision had fairly recent parallels in Europe.

Among primitive people the idea of kinship is for the most part too potent socially to allow much room for caste-like growths. Even where royalty was elaborately divine, as in Polynesian Tonga, every king and noble had acknowledged kinsmen in all strata of society. Substantially the same situation existed in native Mexico and Peru, where the local commune of actual or reputed blood relatives remained the basis of society beneath the politico-military superstructure. Africa, especially in the east, shows some approaches to caste, presumably under indirect influences from higher civilizations; smiths are often a sort of needed but tolerated out-caste comparable to the Jews in mediaeval Europe; and in some districts pastoral Hamitic invaders like the Wa-huma have made themselves a noble caste among the native farming population. Somewhat reminiscent of caste is the division of the Arabian population into Bedouin and town dwellers, and of the native American Southwest into farming Pueblos and roving Navajo and Apache; these, however, are cases of culturally and politically independent units segregating along caste-like lines, not of subdivisions within one such unit.

CASTELAR Y RIPOLL, EMILIO (1832-99), Spanish statesman, journalist and historian. Castelar obtained his doctor's degree in 1853 in the faculty of philosophy at the University of Madrid. The following year he distinguished himself by a brilliant oratorical defense of the liberties of the individual. This led to his appointment to the staff of *El tribuno*, and he served on various journals until 1863, when he founded his own organ, *La democracia*. His work as a journalist was as effective as his masterly eloquence in educating the Spanish people in the principles of constitutional government. In 1856 he was appointed to the chair of history in the University of Madrid, where his lectures drew large audiences. The educated bourgeoisie were enthusiastic about this man who, in a period of decadent politics, discussed the burning political questions of the day eloquently and beautifully, elevating them to the plane of general principles and interests. His antimonarchist activities resulted in 1865 in the suppression of his paper and the loss of his chair. The following year he fled to Paris to escape execution for complicity in republican plots. He returned to Spain during the revolution of 1868 and became leader of the individualist republican group, whose program he had presented in the columns of his paper and in his *Fórmula del progreso* (Madrid 1867). Rather than split the republican ranks he cooperated for a time with Pi y Margall and his socialist and federalist republicans. But after the republic was established by the National Assembly in 1873 the constant disorder and the overthrow of two presidents in a few months influenced Castelar, as the third president, to break with the federalists and to use a reorganized army to restore order. This action, coupled with conservative tendencies which had been strengthened by the exercise of power, caused him to lose the support of the more radical republicans but permitted him, after the restoration, to be the

respected and respectful adversary of the crown. He retired from active political life in 1893, still believing in a republic as the ideal form of government but opposing its introduction by violence. Castelar and Pi y Margall are the most representative figures in the history of the republican party in Spain.

Castelar was endowed with a powerful imagination but rebelled against any severe mental discipline. He divided his activities as a writer between history and literature but left no work worthy of his ability in either field. His historical writings are, more strictly, brilliant literary works. He showed a very marked tendency to judge the personalities and events of the past according to his own ideals fashioned from the individualistic and democratic principles of the French Revolution.

CASTELLIO, SÉBASTIEN (1515-63), Swiss Protestant theologian and freethinker. Castellio, who early evidenced a passion for knowledge, worked as a tutor in a noble family in order to pursue his studies at Collège de la Trinité, Lyons. At twenty-five he met Calvin in Strasbourg and on his recommendation became in 1541 principal of the Collège de Genève, a center of Greek learning and study of the Scriptures. His first work, the *Dialogi sacri* (Lyons 1540), was a series of vivid scenes out of the Bible, a manual for schoolboys which went through many editions and was translated into many languages. Castellio was profoundly interested in classical antiquity and thought of Christ as a moral teacher. His evangelical humanism made of him an antagonist of Calvinist orthodoxy and an advocate of tolerance. In 1544 he came into open collision with Calvin when he interpreted the *Song of Solomon* as an ancient love poem rather than as a revelation of the true relation between Christ and the church and demanded its exclusion from Holy Scripture. Likewise he denied that Christ's descent into hell was a punishment and disagreed with Calvin's theory of predestination. He removed to Basel, where after some years of poverty he became professor of Greek literature at the uni-

versity. His *Biblia sacra latina* (Basel 1551), an annotated translation, was his largest work, but his most famous was the *De haereticis an sint persecutendi . . . doctorum virorum sententiae* (Magdeburg 1554), which was immediately translated into French. Here Castellio set forth his reasons for opposing the persecution of Servetus, arguing that the burning of heretics was in the spirit neither of Christ nor of reform. The preface, bearing the pseudonym "Martinus Bellius," is one of the mother documents on freedom of conscience. In *Contra libellum Calvinii* (n.p., c. 1554) he answered the reformer's reply. In an unpublished work, *De arte dubitandi et confidendi et sciendi et ignorandi*, Castellio as a precursor of Descartes made a plea for the use of intelligence even in matters of revelation.

CASTILLA, RAMÓN (1707-1867), Peruvian politician and soldier. Castilla served in various important military and political offices and became known as a man of strong character and energetic action. In 1844 he led a successful revolution against the dictator Vivanco, was elected president of Peru the following year and for twenty years thereafter exercised a preponderant influence in the country. During his first administration (1845-51) public instruction was improved, the army reduced and reorganized, the navy enlarged, the first telegraph lines were installed (1847), a railroad was constructed (1851), a budget system introduced, the public debt consolidated and in part refunded (1848), the exploitation of guano reorganized and that of nitrate begun, immigration and colonization were subsidized and, in administration, law was observed and men were employed irrespective of party affiliation. In 1854 Castilla took over and led to success the liberal revolution which had broken out against his successor Echenique and again took office as president in 1855. This revolution was accompanied by two important social reforms—the abolition of the personal tribute paid by the Indians since colonial times and the compensated emancipation of Negro slaves. During his second administration (1855-62) anarchy, party strife and attempts at assassination caused Castilla to rule with an iron hand. As a liberal he forced the novel and radical constitution of 1856 and as a conservative he

brought about the adoption of the constitution of 1860 which was moderately conservative and modeled after that of the United States. It recognized the Roman Catholic religion as the state religion, restored ample power to the president, but retained the right of association. This constitution remained the fundamental law of the land until 1920.

CASTLEREAGH, ROBERT STEWART, VISCOUNT, SECOND MARQUIS OF LONDONDERRY (1769-1822), British statesman. Castlereagh, who was born in Ulster, Ireland, was elected to the Irish House of Commons in 1790 and became chief secretary for Ireland in 1798. He suppressed the Irish rebellion of that year and was instrumental in bringing about the parliamentary union of Ireland with England. In 1800 he entered the British House of Commons. Castlereagh's chief contribution to history was made during his tenure of the British Foreign Office during the years 1812 to 1822. The last European coalition which finally brought about Napoleon's downfall was largely his work, and no other man had a greater influence on the reconstruction of Europe and on the scheme of a European alliance. In reconstruction his main object was to produce a "just equilibrium" in Europe. For this purpose he wished France reduced to her old frontiers and Russia kept east of the Vistula. He succeeded in his first object and indeed had to repress the desire of the allies for a vindictive peace in 1815. In his second object he failed, but by building up Prussia and bringing her to the Rhine and by encouraging Austrian influence in Italy he made a central Europe strong enough to preserve the balance against the two other powers. The European Alliance, too, was mainly his creation. This idea, born in the Third Coalition, was in its origin a guaranty of Europe against France by the four Great Powers, which promised mutual aid to one another. At Vienna Castlereagh even considered extending this guaranty to all Europe, including the Turkish dominions. Subsequently, however, he preferred the system of diplomacy by conference to settle all questions disturbing the peace of Europe.

In contrast to Alexander, whose own ex-

pedient, the "Holy Alliance," was purely moral, and to Metternich, who wished to use the alliance to repress the revolutions which broke out in Italy in 1820 and 1821, Castlereagh had always denied the right of the European Alliance to intervene in the internal affairs of other countries. He protested, at first secretly and then openly, against this misuse of power at the conferences of Troppau (1820) and Laibach (1821). After the outbreak of the Greek revolution he agreed to attend another conference where he hoped to settle by round table diplomacy the threatening Russo-Turkish and Franco-Spanish disputes as well as the problem of the Spanish colonies. His suicide in a fit of insanity resulting from overstrain immediately before the Congress of Verona (1822) caused the failure of these plans. The idea of diplomacy by conference was never understood by public opinion in Castlereagh's day and was associated with the repressive use which Alexander and Metternich made of it. It was, however, the only attempt to form a permanent diplomatic conference of the Great Powers previous to 1919.

CASTRO, CIPRIANO (1861-1924), dictator president of Venezuela from 1899 to 1908. He spent his early years in the cattle industry and for a brief time served in the national congress. He took possession of the government in 1899 by an armed revolt, and because of his shrewdness and daring became known as the "Lion of the Andes." He was vain and uneducated, and in his domination of the courts, congress and state governments somewhat corrupt and wholly despotic. Yet his regime was not without benefit to Venezuela. He developed its resources, promoted internal improvements such as roads, parks, public buildings and a telegraph system, had legal codes promulgated and encouraged education. But he became notorious because of his relations with foreign countries. He dreamed of founding a great nation composed of Venezuela, Colombia and Ecuador, of reviving the old unity of the days of Bolívar. To realize this ambition he encouraged the liberal party of Colombia in its revolt which resulted in strain-

ing relations with that country from 1901 to 1905. Of much greater international notoriety, however, were his difficulties with European powers arising from the repudiation of Venezuela's public debt and the unwillingness to recognize the claims of foreigners for injuries to their persons and property. As a result England, Germany and Italy blockaded Venezuelan ports from December, 1902, to February, 1903. It was this situation which led to the enunciation of the Drago Doctrine and the Roosevelt corollary to the Monroe Doctrine. Castro's defiance contributed greatly to his reputation in Spanish America as a defender of the weak. In the years following the settlement of the Venezuelan affair by 'The Hague Tribunal he embroiled himself with Belgium, Holland, France and the United States. But when Castro was compelled in 1908 to go to Europe for medical treatment, Juan Vicente Gomez took advantage of his absence to consolidate his own power. The "Lion of the Andes" was never able to return to his native land.

CASTRO, JUAN DE (dates of birth and death unknown), Spanish economist of the late seventeenth century. Castro expounded notably rigid and consistent mercantilist doctrines in his *Memoriales para el entero conocimiento de la causa, que destruye, y acaba la monarquía de España* (Madrid 1669?). Likening treasure to the "blood of Spain," he repeatedly identified it with wealth and exhorted his compatriots to correct the unfavorable balance of trade, which was carrying Spain's gold and silver to foreign lands, impoverishing the former and enriching the latter. Where mercantilists of other countries sought the accumulation of specie through a highly favorable balance of trade, Castro's desideratum was the retention of the

Mexican and Peruvian treasure of Spain by balancing the trade with England, France, Holland and the Italian city-states. His program consisted of supplying the home market and the colonies with Spanish manufactures, excluding foreigners from trade with the Hispanic colonies, carrying Spanish goods in Spanish ships, building a strong navy and maintaining a large army, restricting the importation of manufactures and the exportation of raw materials and increasing the population. Castro's *Memoriales* and miscellaneous pamphlets on the American slave trade abound in numerical data, which, for lack of better information, are occasionally useful to critical scholars.

CASUAL LABOR is that which is hired for short periods, more or less indiscriminately. It is to be differentiated from labor, skilled or unskilled, which is selectively chosen with a degree of certainty to fill the needs of seasonal industries. Examples of such seasonal labor are the skilled workers in the building industry, who may work irregularly on short jobs and possibly for a number of different employers during the year, as well as a large proportion of the semi-skilled operatives in the garment industries. Around these seasonal industries, however, may develop large reserves of casual, semi-skilled or unskilled labor hired at the peak and discharged in the slack season with no assurance of reemployment. The proportional distribution of these seasonal and casual workers is largely a matter of the economic organization of the industry and of the workers. All migratory labor on construction camps and in the harvesting of crops is in reality casual labor but it presents such a vast number of special problems that the term "casual labor" is usually narrowed to include only non-migratory types. This type is best illustrated by the wharf and dock labor of loading and unloading ships.

The existence of large classes of casual labor had its origin in the rise of capitalistic production for the market by large numbers of individual producers. It assumed serious proportions when the railroad and the steamship made the market world wide; by the aid of mass production and the subsequent rapid technological development thus made feasible a situation was

created in which each concern experienced vicissitudes of business fortune independently of concerns in other industries and even in large measure independently of other concerns in the same industry. It is to this complex market situation that we must turn in seeking the fundamental causes of the system of casual labor.

Each firm, being subject to its own independent fluctuations in demand, seeks to keep subject to engagement sufficient labor to enable it to handle its peak loads. The time of incidence of these peak loads is imperfectly predictable. Their recurrence may or may not be regular and may or may not coincide with recurrence in other enterprises, even in the same line of business. In such a situation reserves or pools, especially of the unskilled or semi-skilled labor, tend to accumulate. These reserves can be completely employed only in the rare event that the peak loads of all the firms occur simultaneously. The result is a permanent group of underemployed laborers, no one of whom is out of work continuously but all of whom are employed only a part of the time.

While practically all industries have these fringes of casuals their presence is a serious problem only in those industries where, due to exigencies of weather and season, to whimsical style preferences of consumers or to other uncertainties arising out of the complexities of modern production and distribution, the individual producer's demand for labor is subject to especially wide and unpredictable fluctuations. In this category fall the marine and longshore industry; many lines of agricultural industry, especially where there has been little diversification of crops; the canning industry; logging and lumbering and the building trades. Certain other industries, notably the needle trades, seem to be coming into this class.

These casuals, it should be noted, are not to be confused with those who are unemployable or whose work is superfluous. They are employable and are intermittently needed. They make up a labor reserve the members of which are called upon often enough to prevent them from emigrating, but not often enough, as a rule, to enable them to make a decent living. The demoralizing effects of a life of casual labor are obvious. Earnings are irregular, uncertain and generally inadequate to provide a decent livelihood for a family, in fact often insufficient to provide a living for the single laborer. Equally sinister from a social point of view are the character and results of the mode of life imposed

on the casual laborer. Irregular work and earnings breed shiftlessness and physical deterioration, and these tend inexorably to reduce the casual to an unemployable, who in turn becomes a charge upon the state. The casualties of our large cities may, so far as earnings permit, establish settled homes of a sort. For the migratory farm laborer and the lumberjack normal family life and a definite relation to the community are impossible. The system of transplanting families, as in the canning and berry picking industries in the United States and in migratory harvesting or sheep shearing elsewhere, raises its own problems of child welfare and of family disorganization.

Such conditions breed discontent, which for the most part, however, has been inarticulate and unorganized. The very nature of the evil makes any organization of opinion or of the workers most difficult. They have no stake in any particular industry and the conservative trade union methods of constitutional, parliamentary procedure could scarcely be expected to appeal to them. With the exception of the longshoremen and the building trades laborers most of these groups, both in the United States and abroad, are unorganized. In Great Britain the great dock strike of 1889 under the direction of leaders representing "new unionism" was a step forward in this direction. The garment industries, prior to their unionization in both Great Britain and the United States, had a far greater fringe of casual workers. The Australian Workers' Union has been singularly successful in organizing labor in agriculture and sheep shearing. But where the casual groups wander from industry to industry even militant industrial unionism cannot succeed, and for many casual groups almost the only outlet for discontent has been through the "one big union" type of organization, either under that name in Canada or under the banner of the I. W. W. in the United States. The I. W. W. finds in the unskilled casual laborer a ready subscriber to its radicalism and its attack upon the conventional union. The results in the way of permanent organization by such groups have been negligible. The I. W. W., however, more than any other organization has succeeded in so dramatizing the casual laborer as to galvanize more powerful trade union and public agencies into remedial action.

Current developments in some industries are tending toward the partial elimination of casual labor. Increasing mechanization of the processes

on which casual labor has been employed reduces the number of casuals employed. The notable achievements of some employers in the regularization of their business operations and the introduction of crop diversification by farming groups have had a like effect. Larger experiments for individual industries have been carried on, notably in the garment industries and in the waterfront occupations. In the garment industries centralized employment agencies under the direction of the union, or often under joint management operated in connection with an unemployment insurance scheme, have done much to reduce the number of casuals and to prevent the influx of new recruits who would swell the ranks of the casuals, and have in some cases even reduced the degree of seasonality. In Great Britain joint endeavors on the waterfronts of Liverpool and London have resulted in reducing the proportion of casual dock workers from 80 to 20 percent. A more limited scheme in the United States was begun on the Seattle waterfront in 1920 and has shown some promising results. The essential features of these schemes have been the establishment of a centralized pool of reserve labor and centralized employment exchanges for the entire industry, with registration, classification and an agreed scheme of priority of employment. There would still remain the necessity of a service as between industries of a given locality or for an industry of nation wide scope, such as agriculture.

CASUALTY INSURANCE. Casualty insurance, the youngest of the three major branches of insurance, comprises a great variety of coverages and is concerned with a wide range of hazards. It includes coverages for the risks not assumed by life or fire and marine insurance. The causes underlying losses covered by this form of insurance are not only greatly varied but are constantly influenced by changing economic conditions, developments in industry, new inventions, changing laws and many other factors. This situation, together with the newness of casualty insurance and its rapid growth, tends to complicate the business and render it somewhat unsettled as compared with the older classes of insurance.

Casualty insurance may be defined as that form of insurance which provides indemnity (1) for losses arising out of the legal liability of the insured for damage to the person or property of others and (2) for certain losses arising out of loss or damage to the person or property of the insured. It is to be observed that suretyship, which is often confused with this branch of insurance due to the fact that a large number of casualty insurance companies write fidelity and surety bonds, is not, properly speaking, a form of casualty insurance.

Casualty insurance is of comparatively recent development; it was virtually unknown before the second half of the nineteenth century. While certain casualty lines appeared first on the continent, casualty insurance as a whole is better developed and gives promise of more rapid growth in the United States. The accompanying table taken from *Casualty Insurance Principles* by G. F. Michelbacher and associates (p. 12-13) enumerates the forms of casualty coverage and gives for each of them the date when it was first written in the United States. The table illustrates the variety of casualty lines and the youthfulness of casualty insurance as compared with the other major branches of insurance.

Liability insurance was at first confined to coverage of the liability of employers for injuries to their workers. This form of protection, known as employers' liability insurance, originated in England following the enactment of the Employers' Liability Act of 1880. Similar legislation

enacted in the United States was promptly followed by a demand for employers' liability insurance in this country.

Public liability insurance was originally written in conjunction with employers' liability, and the additional coverage was probably embodied in endorsements attached to employers' liability insurance policies. The first public liability coverage provided insurance for manufacturers and other employers of labor against their liability for personal injury or death caused to members of the public by reason of the employers' various operations. But additional forms were soon developed. By 1900 public liability insurance was available not only to employers but also to physicians, surgeons, dentists, owners and operators of elevators, owners and tenants of buildings and contractors or others liable for injuries resulting from their operations, including the use of teams. Of the forms of public liability insurance other than automobile, which comprise the so-called miscellaneous public liability lines, the most important is owners', landlords' and tenants' public liability. The coverages provided under manufacturers' and contractors' public liability rank next. So far as the volume of business is concerned the malpractice liability lines, applying to physicians, surgeons, hospitals, dentists and druggists, have remained comparatively unimportant. With the introduction of motor vehicles and tremendous increase in their use the volume of automobile public liability insurance has grown very rapidly. Between the years 1923 and 1929 this business increased 130 percent in the United States.

The earliest distinctive form of property damage liability insurance covered liability for damage to property caused by the operation of automobiles, and during the first two decades of the twentieth century there was comparatively slight demand for other forms of property damage liability insurance. Moreover, the early development of this business, as applied to risks of a general nature, was also restricted by statutory limitations. These limitations were, however, gradually removed, permitting the extension of property damage liability insurance into new fields. Thus in New York it was not until 1922 that the law was amended definitely to permit insurance carriers to write this form of insurance.

Burglary, theft and robbery insurance had its origin in England. In the year 1787 the first recorded attempt was made to establish a com-

pany to provide insurance against risks in this field. This attempt as well as other plans for organizing companies during the century which followed was apparently unsuccessful. These coverages were introduced successfully by a company of Glasgow, Scotland, and it was not until 1889 that any appreciable amount of this business was written. The earliest forms of burglary insurance written in the United States were the residence and mercantile open stock forms which appeared in 1885. Bank burglary and mercantile safe coverage were offered in 1892 by the Fidelity and Casualty Company of New York, which for a number of years was practically the only company transacting this business. By 1900, however, several other companies had become actively interested in writing this business. This class of insurance, once introduced, was gradually extended to cover related hazards such as theft, larceny and robbery. Moral hazard is one of the most important factors which enter into the writing of all burglary lines, especially residence burglary, theft and larceny insurance, where this element is regarded by some carriers as constituting as high as 90 percent of the underwriting considerations involved. Moral hazard is also present in mercantile open stock burglary insurance because of the opportunities for fraudulent or fraudulently inflated claims.

Health and personal accident insurance were among the earliest casualty lines written. This business has been handled largely by life insurance companies, but the casualty companies are assuming a prominent position in the field.

Of those casualty lines which are available to employers to indemnify them for damages caused by accidents to their physical plants, steam boiler insurance is undoubtedly the oldest. This is the branch of casualty insurance which deals with the hazards of power producing mechanisms. About 1854 an association was organized in England for the prevention by frequent inspection of steam boiler explosions. While this association did not engage in the business of insurance it was absorbed a few years later by a company organized for the purpose of insuring these risks. In 1866 there was formed in Hartford, Connecticut, the first American company which undertook to meet the need for insurance protection against the risk of the destruction of life and property by the explosion of steam boilers. As an important accompaniment of the insurance protection to be provided an inspection service was guaranteed. In 1867 this pioneer company began writing policies and in-

specting boilers, thus launching a new form of insurance coverage in this country. Other companies soon entered the field and adopted the methods of accident prevention inaugurated by the original company. With the development of sources of motive energy other than steam the methods of boiler insurance have been extended to the underwriting of a variety of machinery hazards. The policies issued indemnify for direct property damage and by endorsement covers may also be granted for indirect losses such as the impossibility of operating the plant at full capacity, inability to fill orders on time or deterioration of materials. Perhaps the greatest service rendered by insurance companies in this field is the establishment of standards of safety and their enforcement by frequent and skilful inspection. Insurance carriers spend three or four times as much for the prevention of boiler explosions as for the payment of losses.

Plate glass insurance originated at practically the same time as power plant insurance. In this line the insurance policy is virtually a contract for the prompt replacement of broken glass, and the rates charged are therefore bound to fluctuate with the changes in the price of glass. A comparatively recent line of plate glass insurance which has shown rapid development is the coverage for automobile glass.

From the point of view of premium volume the automobile casualty lines—public and property damage liability and collision insurance—are the most important; workmen's compensation insurance ranks second and accident and health insurance third.

While insurance is primarily a device for the accumulation of premiums from all those who are exposed to a hazard and for the distribution of the funds so collected to those who suffer as a result of that hazard, in the field of casualty insurance there is a marked tendency toward the development of accident prevention as an integral part of insurance. One of the earliest applications of the principles of accident prevention was in connection with boiler insurance, but this preventive work has been progressively developed in connection with other casualty lines. At present casualty companies have undertaken through cooperative action important projects designed to reduce accidents and thus effect a saving of life and limb. For some casualty lines the cost of prevention work appears as an important factor in rate making.

In rate making the charge is developed in two parts, the so-called pure premium, repre-

senting loss cost, and the expense loading to provide the necessary expenses of the transaction. For the purpose of establishing the rates which appear in the manuals risks are divided into broad groups or classifications on the basis of similarity of hazard, the same manual rate being assigned to all risks within each group. This procedure would be entirely satisfactory if all risks within the group were exactly similar. As this, however, is not the case, systems of merit rating have been devised for application to the individual risk, to measure the extent to which the particular risk varies from the average of its class and to reflect this variation in the rate for the risk.

In the early stages of the development of the business of casualty insurance it was necessary to rely chiefly upon judgment for the establishment of rates applicable to the various forms of coverage. With the growth of the business, however, experience accumulated and became available for use as a basis in rate making. Since the experience of no one company is in general broad enough for accurate rate making, the pooling of the experience of all carriers is necessary for the making of equitable rates. The casualty insurance carriers early recognized this need and formed organizations to give attention to the problems in each field as soon as the volume of business had reached an appreciable size.

Through these cooperative efforts of the companies it has been possible to introduce and apply with increasing effectiveness the principles of actuarial science in the making of rates for casualty insurance. Due to the volume and the characteristics of workmen's compensation insurance it has been possible to introduce greater refinement and accuracy in the rate making for this line than for the other forms of casualty insurance. If all forms of insurance are considered, workmen's compensation may be said to rank next to life as regards the extent of the application of the principles of actuarial science.

Like other insurance carriers casualty companies are subject to a certain measure of regulation by the state. In the United States the insurance departments of the several states are at liberty to examine the books of the companies and to require the submission of reports in order to determine that the companies are solvent and responsible, investing their funds as required by law, maintaining necessary reserves and otherwise complying with the laws of the

states in the conduct of their business. The great tasks of casualty regulation are to assist the companies in bringing about greater standardization in the business generally, to promote the sound development of the companies and otherwise to protect the interest of the public. Casualty regulation is also distinguished from the regulation of other forms of insurance by the greater freedom allowed to the companies in their investment policies and the greater caution required in the establishment and maintenance of proper reserves.

CASUISTRY. The word casuistry is commonly used in two senses. In the first place it may mean simply the development of moral principles through their application to special cases. In the second place it may mean applied morality which has for its purpose the justification of questionable activities and which proceeds by discovering subtle and hypocritical exceptions to general rules of conduct. That there is usually no distinction drawn between these two uses of the word is a consequence of the common belief that morality is incapable of rational treatment, being either a matter of individual taste or a subject upon which some authority, either God or conscience, has given us the last word, and upon which further discussion is therefore useless and dangerous.

In its primary sense, as the particularization of moral rules, casuistry is the natural culmination of ethics. Although treating of the application of ethical judgment to individual cases, it deals also with general or universal propositions, and such judgments can be distinguished from those of general ethics only by a comparative narrowness

of scope. Thus the proposition that lying is bad would be regarded as ethical, and the proposition that lying to save a friend's life is good would be regarded as part of casuistry. Casuistry, then, stands in the same relation to ethics or moral philosophy as astronomy does to physics. In the absence of an adequate general doctrine of ethics it must naturally find itself more akin to pre-Ptolemaic astrology than to modern astronomy. To this internal dependence upon a discipline which has scarcely emerged from the pre-scientific stage, one may attribute a good deal of the dishonor into which the word casuistry has today fallen.

Casuistry has usually flourished at times when a generally accepted system of ethics has demanded development along new lines because of changing economic, political or intellectual conditions. In the West casuistry has operated particularly upon the transplanted stoic morality during the early Roman Empire, upon the ethical code of the Pentateuch in the Talmudic and post-Talmudic explication of the exiled Jews and upon the received Christian morality during the period when the agricultural organization of European society was breaking down. In the *Summae casuum conscientiae* (Casebooks of conscience), written from the thirteenth to the seventeenth centuries and meant especially for use in the confessional, the process of particularization in ethical doctrine was carried to an extreme point. Since Kant, however, there has been a strong tendency, outside of the Catholic church, to restrict academic inquiries in morality to a more general and abstract plane.

Close analogues of these casuistical processes are to be found in the development of Roman law, which from the fifth century B.C. to the sixth century A.D. was considered to be essentially an interpretation of the Twelve Tables—and as well in the judicial development of American constitutional law. Such decisions as those ruling that the "due process" clause of the constitution forbids the legislative limitation of working hours for bakers to ten per day but does not forbid the limitations of the miner's working day to eight hours suggest that there is nothing peculiarly mediaeval, religious or scholastic in the difficulties and concomitant dangers of casuistry.

Today a growing appreciation of the dependence of ethical values upon factual conditions and a general disregard for the element of value which cannot be stated in terms of existence have relegated modern casuistry to an unavowed

place in the literature of the social sciences. Except for the fact that ethical discussion is nominally disavowed, psychologists who tell us how we ought to bring up our children, economists who tell us how we ought to adjust the currents of distribution, political scientists who describe our duties to the state and jurists who tell us how people and, in particular, how judges ought to act, are all continuing a discipline which is coeval with man's command over rational method and interest in conduct.

The methodology of casuistry has commended itself to modern law teachers and sociologists as in other centuries to the Jesuits and Talmudists, because of the ease with which concrete problems are assimilated and vitalized in the student's experience. The difficulties of casuistry on this plane are, in a measure, the difficulties of all scientific method. On the one hand, those who have looked upon the decision of particular cases as a merely mechanical application of general principles have run into (or illicitly evaded) the logical difficulty that particular conclusions cannot be derived from purely general premises—a difficulty which shows itself in a question that is always relevant and usually critical and never answerable on the sole basis of general rules, namely: "Which of several admitted principles is, in the light of all circumstances, most applicable to this case?" On the other hand, those who have regarded the decision of special cases as a problem independent of general principles—and students of the case method have regularly professed a nominalistic disregard of abstractions—have run into the more serious difficulty that no unified science and no inference is possible on the sole basis of individual cases. Any two cases, in ethics as in law, can be distinguished, and a refusal to enter the realm of abstractions in an open and critical spirit for the valuation of different "elements" of "principles" has led either to the differentiation of cases on trivial grounds or to the subsumption of cases demanding different treatment under a single rubric. It is on these points that the most important criticisms have been directed against casuistical method, whether employed by Greek sophists or by students of the common law, by Jesuits or by the religious teachers of the Protestant, Jewish or Mohammedan sects.

CASUS BELLI is a term used to designate any event which is alleged by one nation as a justification of war against another. The casus belli is thus the avowed occasion of war. Historians usually class it with the "immediate" causes of a war.

It would be impossible to enumerate the various acts or omissions which have been considered at different times in the history of nations as casus belli. They range from the invasion of territory to the failure to fire an appropriate salute in honor of the visit of a reigning prince. The mutilation of the ear of an English sea captain named Jenkins precipitated the war of 1739 between England and Spain. At first called Jenkins' Ear War, it later became part of the War of the Austrian Succession. A dispute over manure led to a bloody war between Peru and Chile in the nineteenth century. A quarrel over a pig is said to have at one time threatened war between the United States and Great Britain.

Since the days of Vattel international jurists who have discussed the circumstances under which wars are to be considered "just" have recognized as casus belli any acts or omissions which seriously attacked the "honor" or "vital interests" of a nation. Any fixing of justifiable casus belli has been rendered impossible, however, by the basic tenets which have prevailed in international law and relations since the Peace of Westphalia. The sovereignty, independence and equality of all members of the family of nations were then firmly established and recognized. It followed from these dogmas that each nation was the sole judge of what constituted a justifiable casus belli.

In such circumstances of international anarchy a casus belli has tended to be only a pretext for declaring war already determined upon for other reasons. Even Vattel, who was very

insistent that wars must be "just," recognized this very realistically although with considerable distaste. "The judicious Polybius," he remarks, "gives the name of *causes* to the motives on which war is undertaken,—and of *pretexts* to the justificatory reasons alleged in defence of it. Thus he informs us that the cause of the war which Greece undertook against the Persians was the experience she had had of their weakness, and that the pretext alleged by Philip, or by Alexander after him, was the desire of avenging the injuries which the Greeks had so often suffered, and of providing for their future safety." The learned author hastens to add: "Let us, however, entertain a better opinion of nations and their rulers. There are just causes of war, real justificatory reasons; and why should there not be sovereigns who sincerely consider them as their warrant, when they have besides reasonable motives for taking up arms? We shall therefore give the name of *pretexts* to those reasons alleged as justificatory, but which are so only in appearance, or which are even absolutely destitute of all foundation. The name of pretexts may likewise be applied to reasons which are, in themselves, true and well founded, but, not being of sufficient importance for undertaking a war, are made use of only to cover ambitious views, or some other vicious motive. Such was the complaint of the Czar Peter I that sufficient honours had not been paid him on his passage through Riga." But then Vattel concludes philosophically: "Pretexts are at least a homage which unjust men pay to justice" (p. 304).

To the instances of Vattel the modern reader will be able to add many others. Either the casus belli alleged is obviously pretended or has remained the subject of great dispute. There is often little connection between the "real reason" and the "pretext." The War of 1812 between Great Britain and the United States was presumably fought over the issues of free seas and impressment, but it had a great deal more to do with the land hunger of the western country. In the Mexican War the United States was able to add vast domains to its territory by considering Mexico's stand on the very debatable question of boundary lines as a casus belli. Each of the opposing views of the United States and Spain in 1898, first as to the responsibility for the blowing up of the *Maine* and then as to Spain's sincerity in promising the pacification of Cuba, has its earnest supporters, and the extent to which Serbia was responsible for the death of Archduke Ferdinand of Austria will probably

always remain an unsettled question. The revelations of Fay, Barnes, Schmitt, Kautsky, Goos, Ponsonby and other post-war writers on "war guilt" cast grave doubts on the validity of more than one public declaration of casus belli in connection with the World War.

Yet the public declaration of a casus belli may be said to have been particularly important in launching the wars of modern times. In the days of dynastic rivalries wars could be carried on for any whimsical reasons at all. Since the people could not protest there was no compelling necessity of convincing them of the "justice" of a war. Moreover, since war was confined to mercenary or professional armies it could be waged without popular participation. But modern war, involving whole peoples, cannot be fought without the general acceptance of a suitable casus belli. Thus casus belli becomes of the utmost importance in the realm of modern political psychology. But the very fact that a country's objective now tends to be the assimilation to national policy of the ambitions of a very few industrial and political leaders, who desire the control of oil, coal, iron, markets, concessions or spheres of influence, makes it impossible to acknowledge actual motives. The more definitely these are on the economic plane, the more imperative it is that the casus belli be upon a high moral plane. "National honor" is more quick to stir loyalty and gain adherence than "national interest"; and since the real causes of modern war are also bound up with cultural, moral and political passions it becomes necessary only to remain silent about those elements in the international complex which are not disinterested.

The belligerent ultimatum of the aggrieved nation states the casus belli best calculated to elicit support; the demand of satisfaction or war puts the leaders of the challenged nation in the position of refusing when there is no guilt or not daring to admit guilt when it exists, since the prospect is condemnation at home and loss of prestige abroad. The result is a reply of righteous indignation and a parading of offended national dignity. The successive steps in the process thus set in motion have by this time carried the respective nations so far that they must now make good their war stand before a watching world. Propaganda secures the popular acceptance of the enunciated casus belli; to doubt is treason, to fail to respond is disloyalty, and either means social disgrace. The stimuli fall safely within the area of the set mental pattern

of national consciousness and the result is enthusiastic support for war on both sides and the release of tremendous energy for the fray. The *casus belli* has served its purpose.

The idea inherent in the phrase *casus belli* has thus proved a great hindrance to the maintenance of international peace. International jurists, powerless to pass effectively upon the disputes of nations, have tended to abandon as futile all discussions as to when wars are "just." The disappearance of the habit of finding *casus belli* must wait upon the development of machinery for the rendering of international justice. All *casus belli* alleged will have to be real reasons and not pretexts when even questions of national honor are included as proper subjects for the arbitration of international tribunals. The League of Nations and the whole movement for the outlawry of war indicate the new trend. In time the very phrase *casus belli* may become obsolete with *casus battel* and *casus duel* and others which have marked the futility of attempting to settle human controversies by force.

CATHERINE II (1729-96), Russian empress. She was the daughter of Prince Anhalt-Zerbst of Stettin, a general in the Prussian service, and in 1745 married Peter, a nephew of the Russian empress, Elizabeth. Left to her own devices by her weak and incompetent husband, Catherine devoted herself to serious reading. From Voltaire and Tacitus she learned to "see things in dark color" and to understand human nature, particularly its frailties; and she mastered the art of cajolery. Her strength and resources gradually unfolded as she systematically plotted to make herself ruler of Russia. This

she accomplished in 1762 when shortly after her husband's accession as Peter III she issued a pronouncement deposing him; from then until her death she occupied the throne.

A genuine enlightened despot, Catherine sincerely believed, until experience altered her views, that mankind could be regenerated through philosophical legislation. For inspiration she looked to her advanced contemporaries; she corresponded with Voltaire, sought advice of Diderot, who came to St. Petersburg in 1773, and of d'Alembert, who refused to come, found her *souffre-douleur* in Grimm and appointed Laharpe tutor of her grandson Alexander. In 1765 she inaugurated an experiment in education with a plan adapted from Locke through which she hoped to produce "a new human race." The next great task which she set herself was the construction of a code of laws, the ancient code having been abolished in 1649. To carry out this work she summoned representatives from all classes except the clergy and serfs and presented them with an "Instruction" compiled from the writings of Montesquieu and Beccaria and concluding with the daring deprecation, "God forbid that after the completion of this legislation any other people should be more flourishing." Catherine was astonished to discover that Russia was totally unprepared for this reformation. She was both astonished and disgusted to meet with opposition from the nobility and gentry who, far from acquiescing in the limitation of their rights over the peasants, were intent on confirming and increasing them. This first period of Catherine's activity, the idealistic phase, ended in 1768 when she abruptly adjourned the commission and turned her attention to war with Turkey, in which she was to find easier success. When, after the conclusion of this war and the suppression of the revolt of Pugachov in 1774, Catherine returned to the task of providing a code, she was in a more realistic frame of mind. Relying on facts and the precedents of Blackstone's *Commentaries* rather than on the abstractions of the *encyclopédistes*, she herself prepared materials for important statutes. By the statute of 1775 she introduced a new administrative and judicial order. By the charter of the nobility, which appeared ten years later, she confirmed the privileges of this class and allowed it to participate in local self-government; the charter of burgesses was less effective, while the charter of peasants never arrived at publication. The rise of a new generation, dissatisfied with

Catherine's moderate reforms and making demands which aroused her increasing antagonism, ushered her into the third and final stage of her career. Her efforts to influence the radicals by publishing a magazine and by writing comedies in which she derided new ideas were without the slightest effect. The events of the French Revolution and particularly the execution of Louis XVI heightened her reactionary spirit, and she resorted to violent measures against the representatives of new opinions. The influential publisher Novikov, a freemason and satirist, was imprisoned in Schlüsselburg; Alexander Radishchev was exiled to Siberia for daring to remind Catherine of her youthful dreams and for suggesting that a *Jacquerie* or even the fate of the English king Charles I might be the end of her present indifference to the demands of reformers.

Whatever Catherine's offenses against liberalism, it was in her reign that self-government and an independent judiciary had their modest beginnings and that the notion of individual dignity began to replace the old Muscovite idea of universal subjection to the person of the monarch. If it was the nobility who reaped most of the immediate advantages of her innovations, at least they extolled the period as their golden age. Catherine's foreign policy, aimed at the expansion of Russia, was eminently successful and had momentous consequences. Through the three partitions of Poland, the first two restoring to Russia the Russian provinces of Poland and the third cutting into the Lithuanian population, she greatly augmented her territory; and her two Turkish wars (1768-74; 1787-92), by which Russia obtained free issue to the Black Sea, inaugurated the Slav policy of her successors.

CATHOLIC EMANCIPATION describes generally the disruption of the penal legislation against Roman Catholics in Great Britain and Ireland. This legislation, which was begun under Queen Elizabeth, was perfected in the

reigns of King William III and Queen Anne. Inspired as much by political fears as by religious hatred, the code left scarcely any loophole through which Catholics could regain their civic rights. Large confiscations of Catholic property were followed by laws designed to break up the estates of Catholics by dividing them among all the children. A Catholic's eldest child could, however, by embracing Protestantism immediately obtain the fee to the entire property subject only to his father's life estate. Catholics were prohibited from acquiring new lands and even from holding mortgages. Practise of their religion was a legal offense. They could have neither chapels nor Catholic schools, and in Ireland it was made criminal even to send children to be educated abroad.

In England Catholicism was already almost extinct when the penal code was systematically organized. Scarcely 70,000 Catholics remained in a population of nearly eight millions, in the mid-eighteenth century. They survived almost exclusively in and around the mansions of a considerable number of landed families, who kept their private chapels and employed priests as tutors for their sons. Their number diminished steadily through individual secessions; whereas in Ireland, which remained overwhelmingly Catholic, the dispossessed and poverty ridden peasantry increased.

The effort to achieve Catholic emancipation consequently took very different forms. In England the Catholics, many of whom held high social rank, were too few to be formidable. The injustice of their persecution was widely recognized and by the middle of the eighteenth century many of the penal laws had become obsolete. These Catholics lived entirely in their own secluded world, but the new generation was anxious to prove its loyalty to the house of Hanover. Yet not until 1778 did they even dare to present an address of loyalty to George III. This was followed at once by the first English Catholic Relief Act, which enabled Catholics to inherit or acquire land and abolished the penalties against "bishops, priests and Jesuits" and against Catholic schoolmasters. But even these concessions aroused the latent Protestant opposition, and in 1780 Lord George Gordon led a mob to London which gained control of the city for a week, wrecking many Catholic houses and chapels and attacking public men reputed to have Catholic sympathies.

These disgraceful riots produced a reaction. The English Catholic gentry, with Charles

Butler as their secretary, gained courage and organized support among politicians. In order to allay distrust in England the English Catholics suggested various compromises in their papal allegiance, which their bishops opposed. In 1791 William Pitt carried the second English Catholic Relief Act, which permitted church building and Catholic schools and permitted Catholics to teach and to engage in the professions. This act required an oath of allegiance, which was not, however, enforced. No further relief was granted in England until 1829.

In Ireland scarcely any important Catholic landowners had survived the rigorous enforcement of the penal code. Informers constantly obtained rewards for denouncing religious worship or other infringements of the elaborate penal laws. Catholics were even officially described as "bondsmen," and as late as 1759 the lord chancellor explained that "the Law does not suppose any such person to exist as an Irish Roman Catholic except for repression and punishment." Only in trade could they find any independent employment. Many famous families had emigrated to Catholic countries, and with their help a direct trade developed which produced a new Catholic merchant class. The landowners of the Protestant Ascendancy frequently needed their financial support and attempted repeatedly but unsuccessfully to enact legislation enabling Catholics to lend money on mortgages. But the British policy in Ireland was to keep the Catholics in a servile state.

Even to receive from George III an acknowledgment of their loyal address in 1760 was more than the Irish Catholics expected, and they shrewdly concentrated upon winning recognition of their legal existence. In 1771 a minor concession was granted to them. In 1774 they gained the right to profess loyalty before a magistrate, and four years later the Irish parliament passed its first Catholic Relief Bill, which still forbade Catholics to own land but granted them long leases. In 1782, after Grattan won legislative independence for the Irish parliament, another act repealed the most extreme decrees of the penal code but still left mixed marriages with Catholics illegal. Until 1782 concessions had been made more or less concurrently in both countries; but after legislative independence Catholic emancipation became the chief issue in Ireland; while in England the penal laws, affecting only a small and influential minority, were already obsolete.

In Ireland the Catholic merchants had as-

sumed the leadership, while the Catholic landowners, dreading reprisals, discouraged all agitation. But the American war and the French Revolution brought new hopes to the Catholics and resulted in a more conciliatory attitude on the part of the government. John Keogh, a Dublin merchant, carried a more courageous policy. When he urged the Irish Catholic Committee, the conservative element, headed by Lord Kenmare, seceded. Keogh then summoned a national assembly of Catholic delegates ostensibly to present an address to the king. The Irish parliament grew alarmed and by the Relief Act of 1792 made important concessions, though still excluding Catholics from the franchise. Keogh then boldly headed a deputation to the king in London, and the Irish parliament was compelled to admit Catholics to the franchise and to abolish almost the entire penal code.

The need for troops and his new alliances with Catholic states in Europe had convinced Pitt that Ireland should be conciliated. Edmund Burke, whose campaign against revolutionary France had given him immense influence, feared revolution if emancipation were withheld. The English radicals were denouncing all forms of oppression, and the Prince of Wales by his secret marriage to Mrs. Fitzherbert had made many Catholic friends. Nevertheless, the concession policy in Ireland was reversed, and a regime of drastic coercion provoked the rebellion of 1798. Pitt then persuaded the Irish Catholics to support him in abolishing the Irish parliament, promising emancipation after the Union. But when Pitt attempted to fulfil his bargain George III interposed and he resigned.

In England the small Catholic remnant was still denied the franchise. The Napoleonic wars prevented further progress, but by 1813 opinion had grown so much in their favor that Grattan almost carried his Emancipation Bill at Westminster. The Irish Catholics had been powerless since the Act of Union, and the influential English Catholic Committee agreed to various concessions which Grattan insisted were indispensable to the acceptance of any Catholic bill in a Protestant country. Their attitude deeply estranged the Irish Catholics, who opposed all compromise.

A new generation of Irish Catholics had found a leader in Daniel O'Connell. He had revived the agitation with great force but preferred to see it collapse rather than compromise. In 1823 O'Connell began again by founding the Catholic

Association, which was financed by penny a month collections and which won the support of the Catholic peasantry. In 1825 an Emancipation Bill passed the House of Commons but was rejected by the Lords. The Catholic Association was suppressed, but O'Connell with unfailing resourcefulness and extraordinary gifts of popular leadership reorganized it at once.

The Catholic Association soon enrolled the entire Catholic population. A rapid succession of prime ministers—Liverpool, Canning, Goderich and the Duke of Wellington—tried vainly to resist the agitation, which assumed a somewhat nationalistic and social character. It was fast growing uncontrollable. In 1828 O'Connell, standing as Catholic candidate in a by-election in Clare, pledged to refuse to take the anti-Catholic oath. His overwhelming victory compelled Wellington and Peel, who had fought him relentlessly, to surrender; they obliged George IV to carry the Emancipation Act of 1829, which abolished the oath and threw open most positions of privilege to Catholics. But the accompanying rise in the property qualification for voting deprived most of the Irish Catholic peasantry of their franchise.

The sequel was politically a bitter disappointment. Catholic landlords entered Parliament from both countries but were still without power to change the administration. Scarcely any important positions were granted to Catholics until after O'Connell's death in 1847. His strongly democratic politics had estranged most English Catholics, and the mutual distrust is only now disappearing. But political emancipation gave more freedom for the subsequent revival of the Catholic church, and the old prejudice has largely died out. It is less strong in England now than in the United States, and there would be no such opposition to a Catholic becoming prime minister of England as Smith's candidacy for the American presidency aroused. A somewhat different prejudice is arising, however, against the Catholic church as the chief body which opposes such tendencies of the age as divorce, birth control and undenominational education.

The Catholic question in America never assumed the proportions that it did in England and Ireland. Nevertheless, in almost all of the colonies Catholics were subjected to discrimination and penal legislation. The notable exceptions were Rhode Island and Pennsylvania, which maintained a consistently tolerant attitude, and Maryland, which was from its incep-

tion and until its conversion into a royal province in 1691 a refuge for colonial and English Catholics. But even in Maryland whenever the Protestants gained control, as they did for a brief period during the Commonwealth, the Catholics were outlawed. Most of the Catholics in the New World naturally settled in Pennsylvania and Maryland.

After the accession of William III severe penal laws similar to those in force in England and Ireland were enacted in the colonies. In Maryland the laws were unusually severe but were not generally enforced. In New York priests were banished and Catholics deprived of the franchise and right to hold office. In Virginia they were not permitted to testify in the law courts. Similar penal codes were enforced in Massachusetts and the other New England colonies.

In the latter half of the eighteenth century public attention centered on political rather than religious questions. A more tolerant spirit prevailed and the position of the Catholics improved. The first Continental Congress made a plea for religious tolerance, and Pennsylvania, Delaware, Maryland, Virginia and Connecticut responded by abolishing the restrictions on Catholics. In many states, however, their rights were limited by constitutional provision or legislation. Rhode Island removed all limitations in 1783. New York followed in 1806, Massachusetts in 1821, New Jersey in 1844 and New Hampshire in 1877.

CATHOLIC PARTIES. According to the teachings of the Catholic church the earthly life is but a preparation for the eternal life hereafter.

It is man's duty to prepare himself to become one with God. The state, the most comprehensive and consequently most effective human institution, must be made to further this end; it must be put in the service of the moral order based on divine laws.

According to the Catholic theory of the state (the Christian natural law, as created by Thomas Aquinas under Aristotelian influence) God is the source of all the state's authority. How and by whom this authority should be exercised is the subject of human law to be determined by the people or their representatives. In this the people are indirectly guided by divine will. A government, once it is created, exists by virtue of God's will and consequently the faithful Catholic should not resist it. A change in government, perchance as a result of revolution, is also a manifestation of divine will, and the Catholic is in duty bound to be faithful to the new regime.

The state, furthermore, has for its purpose the encouragement of the individual in the development of his physical and spiritual powers for the common good. In the narrower sense its main purpose is the realization of natural morality. Since man is born into the world a free and independent being, the state must respect the rights of human personality. It must respect also the rights of private property and above all the rights of the family, the most important of which is the educational guidance of children. The church is independent of state authority. It is the state's task to support the church in the exercise of its duties. It should be emphasized that these principles do not deal with the form of the state. The church allows wide freedom in the details of politics, provided they are subordinated to the ultimate moral purpose.

The French Revolution, having attacked the privileges of the clergy, proceeded, under the influence of the Enlightenment, to attack the existing organization of the Catholic church. The Civil Constitution of the Clergy of 1792 was an attempt to separate the church from papal authority and by making the clergy elective to give the church a democratic basis. The pope and the priests resisted successfully and out of their spiritual conflict and political struggle emerged the conservative traditional conception of the state. The theory was first clearly formulated by Bonald in his *Théorie du pouvoir politique et religieux dans la société civile* (1797), recast in brilliant language by de

Maistre in his *Du pape* (1819) and later developed and refined to fit political reality. According to this concept Catholicism, deprived of state support, seeks closer union with the papacy. From this the epithet ultramontanist was correctly applied to the Catholic political movement, which is decidedly hostile to the Enlightenment and all its principles. Politically its chief tenet was opposition to the new developments in France. After the revolution of 1830 many alert Catholics realized the limitation of such a program, and adherents were found for a new group led by Lamennais, Lacordaire and Montalembert which stood for close union with the pope and urged upon the French state the view that France seek its salvation in the church. At the same time it was ready to compromise with democratic developments, and it repudiated the monarchy and the émigrés on the condition that the church be granted freedom from and in the state, especially freedom of teaching. This position was condemned by the pope in 1832. After 1848 the party, encouraged by bourgeois elements as a makeweight against the feared socialism, gained new strength.

Under Napoleon III the Catholic group supported the empire, encouraging imperial aggression wherever it might be made to serve the propagation of the faith. Montalembert was instrumental in winning the concession that education be left almost wholly to the church and the religious orders. The close alliance of the church with political reaction led ultimately, under the Third Republic, to the elimination of the church as a political factor. In 1892 Pope Leo XIII's encyclical *Inter innumeras sollicitudines* made a distinction between the government, which it stamped as irreligious, and the republic, which it ordered Catholics to accept. This policy brought to the front Conservateurs, Ralliés, Catholic republicans. A small group, the Sillon, founded in 1899 by Marc Sangnier, which attempted to effect a rapprochement with the state on a democratic basis, was condemned by the pope, but the Sangnier group received some impetus on a new basis in 1926 after the pope had condemned the nationalistic attitude of the Action Française, a Catholic-royalist party under the leadership of Léon Daudet and Charles Maurras.

In Germany the Catholic political movement began with secularization as a struggle for the freedom of the church from enlightened absolutism, irrespective of whether the government was Catholic or Protestant. Between 1820 and 1848

there were in all the South German diets deputies who in close alliance with the curial movement within Catholicism worked for the free functioning of the church in the state and fostered church influence in public schools. The political ideology is traditionalistic throughout. This is also fundamentally true of Goerres, who was originally a follower of the French Revolution but who later drifted into romanticism which, as a literary movement, showed considerable Catholic leanings. In reality only the Catholics west of the Rhine, such as the Reichensperger brothers, were liberals. In Prussia the fight between the Catholic church and the state was linked up with the demand of the state that the church accept mixed marriage. In 1848 the Catholic protagonists made use of the revolutionary movement to secure complete liberation of the church from the state. For this purpose a Catholic group was formed temporarily in the parliament of Frankfurt. In Prussia a Catholic group was formed in 1852, assuming the name *Zentrum* in 1859 from the location of its seats in the center of the chamber. The representatives of political Catholicism before 1871 stood for the unification of the German speaking peoples, including those of Catholic Austria, into one state.

After the formation of the German Empire a Center party was organized which immediately gained a considerable number of seats in the Reichstag. Its demand for special constitutional provisions for the protection of the liberties of the church and for German intervention on behalf of the papal state in its struggle against the forces of Italian unification aroused Bismarck's hostility. By cleverly utilizing anti-Catholic liberal sentiment he led a systematic fight against the party and the church—a fight which Deputy Virchow christened *Kulturkampf*. Bismarck hoped to crush the church through the authority of the state; but outraged by his acts of violence the faithful turned more and more to the Center party as its only defense. Although government measures forced the latter into unconditional opposition, its leaders remained conscious of the fact that an improvement in the political position of the church could be effected only by co-operation with the government. This was the goal of Windthorst and was attained by him when Bismarck withdrew from the National-Liberal party in 1879, effecting financial reforms through the votes of the Center, which now put forward its constitutional demands. These were opposed to the extension of federal authority in

the separate German states and were particularly concerned with safeguarding popular representation, the only means of pressure on the government. With this turn Bismarck began the liquidation of the *Kulturkampf*. On the whole, the Center cooperated, but it often joined the Left opposition and only after Bismarck's dismissal did it become really friendly to the government. It did not, however, surrender the possibilities of opposition, as in this way it could attain more of its special aims. The party held the balance of power between Right and Left, justifying its shifts to the voters by referring to the interests of the Catholic church.

The support of the party does not come from a socially homogeneous group but from agricultural as well as industrial workers, employers and, since the introduction of woman's suffrage, about 75 percent of the women of the country. To hold together these divergent economic and social interests the party has always followed a middle course, with a growing democratic trend. During and since the war the party has opposed annexation and favored immediate peace and internal political reforms. The peace resolution of 1917 was chiefly the work of Erzberger, the leader of the party's Left wing. Following the revolution the party declared itself immediately for the republican form of government. It assumed temporarily the name *Christliche Volkspartei*, but soon returned to its old name. In the National Assembly it formed the so-called Weimar coalition with the Social Democrats and the Democrats and thus succeeded in securing constitutional safeguards for the rights of religious institutions, although it has not as yet succeeded in doing away with the federal school act. Owing to a similar coalition the party enjoys a strong position in Prussia, where it effected the conclusion of a papal concordat. Wirth, the leader of the party, inaugurated the policy which led to the arrangement with war enemies and to the reparations settlement. This policy was consistently upheld by the party. After the war the Bavarian deputies seceded to form the *Bayerische Volkspartei*, which leans slightly more to the Right than does the parent group and derives support exclusively from the peasant class. Under the influence of the higher clergy the Center party itself has recently leaned more to the Right, although it has clung to its old strategy of working alliances with either side. In the general elections of recent years the party lost somewhat in parliamentary representation, but it regained a number of seats in 1930.

The Austrian Christian (Catholic) Socialist party was formed under Karl Lueger's leadership in the eighties in opposition to the predominant liberalism. This party, of middle class character, reflected the current bourgeois anti-semitism. By the end of the century it had absorbed the older loosely organized Catholic conservative group, which brought with it large masses of agrarian voters (especially the more prosperous peasants) and small traders. Strongly anti-Social Democratic, it set up its own agricultural cooperatives and opposition labor organizations. In domestic policy the party stood for the organization of a southern Slav state within the Austrian Empire to offset the influence of Hungary and to secure German supremacy. Though in reality highly conservative, the Christian Socialist party formed a coalition with the Social Democrats after the war and voted for the radical democratic constitution. In 1923 it became the strongest single party and combined with the Greater Germany party against the Social Democrats. In recent years the Christian Socialist party, led by the priest Ignaz Seipel, has tended to join with the Heimwehr Fascisti, largely as a step toward restoring the Hapsburg empire. The Labor wing, led by Kunchak and never more than a minor element in the party, has been reluctant to follow this move.

Although the elements for the creation of a Catholic party were present in Italy, the struggle of the Risorgimento against the pope which tended to create a separate Catholic political group was itself the circumstance which prevented the formation of a Catholic political party. Since the popes did not recognize the Italian monarchy, whose unification campaign had caused the abolition of their temporal power, Catholics were prohibited by the papal bull *Non expedit* from participating in national elections. They were, however, allowed to vote in local governing bodies, which they did with increasing success. In 1900 a large number of municipalities came under Catholic influence. In the parliamentary elections of 1902 Catholics as such participated for the first time with papal acquiescence, and in 1905 Pope Pius X repealed the bull which forbade political activity. In 1909 the Catholics, as the People's party, adopted an attitude friendly to the national constitution and above all opposed to radicalism. The priest Romolo Murri, who led the radical democratic Catholics, did not join the party and took his seat on the Left, as a consequence of which he

was excommunicated. Thereafter, the Unione Cattolica Popolare Italiana, enjoying papal support, was the only Catholic party. During the war its policies were very moderate and it favored Italian neutrality.

After the war the group gained additional strength because of the conciliatory attitude of Pope Benedict XV toward the Italian state as well as because of the introduction of woman's suffrage. Under the energetic leadership of the priest Luigi Sturzo the party, since 1919 called the Partito Popolare Italiano in an effort to disguise the religious basis of its motivation, took a democratic trend, favoring conciliation in international relations, social reform, agricultural reform, administrative decentralization and especially freedom of ecclesiastical education. The Popular party and the Christian (Catholic) trade unions helped to suppress the public service strikes of January, 1920. During the syndicalist uprisings the party took its lead from its middle class elements, and its small farmer supporters cooperated with the Fascisti. One member of the party sat in Mussolini's first cabinet. From 1919 until 1921 it was the third strongest party in Italy, but like all other parties in that country it finally succumbed to the Fascist dictatorship. Its more conservative elements joined the Fascisti and Sturzo went into exile under orders from the Vatican.

CATO, MARCUS PORCIUS (234-149 B.C.), called "the Elder" or "the Censor," one of the great figures of the early stage of Roman imperialism. To the later Romans, especially to Livy, he was the model citizen, the exemplar of the older Roman virtues of severity, simplicity and patriotism. A brilliant and successful soldier, a good lawyer, Cato confined his political activities to bitter opposition to the popular and dominant family of Scipios, all of whom he pursued with a personal and relentless animosity. His famous purge of the senate in 184 B.C. from which he derived his by-name was, it may be, motivated at least as much by political considerations as by a horror of vices to which he was not as much averse as later legends indicated. That such a man would set his face against Greek fashions in thought or conduct or Greek practices in religion was almost inevitable. He would probably have done so even had the Scipionic circle, which he hated, been less markedly philhellenic. But he was honestly shocked when the Greek Carneades offered to defend both sides of a question on successive days and he was filled with a real horror at the Bacchanalian rites with their mingling of sexes and intrusion of new divinities. Yet his fear of foreigners, his ruthlessness to possible enemies of Rome, even his contempt of women, were not wholly derived from the stark conservatism of

the Sabine ploughboy. He shared without knowing it the state ideal of Plato and Aristotle, a small community of equals dominating a large but still limited area in which groups and sub-groups were maintained in due subordination. His permanent importance lies in the attraction which this ideal, despite its obvious futility, still exercises over many minds.

Of his works his book on farming, *De agri cultura* (ed. by H. Keil, Leipsic 1895; tr. and ed. by F. Harrison in *Roman Farm Management*, New York 1913, p. 19-50), has survived in a revised form. It is an excellent manual written by a real farmer and is invaluable for the economic history of the ancient world. His other works, *Origines*, the first prose history in Latin, and his orations, survive only in quotations.

CATTANEO, CARLO (1801-69), Italian patriot and social philosopher. Cattaneo was a favorite student of G. D. Romagnosi and he early attained a position of importance in Italian intellectual life. When the Revolution of 1848 broke out in Italy he became the leading spirit of the Milanese insurrection against Austria, the events of which he later vividly recorded in his *Insurrection de Milan en 1848* (Paris 1848). After the recapture of Milan by the Austrians Cattaneo emigrated to Lugano, in Switzerland, where he taught philosophy from 1852 until 1865. Cattaneo never abandoned his original allegiance to the federalistic principle of unification and refused to take any active part in the Italian monarchy, although he was summoned to Naples by Garibaldi in 1860 and was later repeatedly elected to parliament. To him federalism worked out on the model furnished by the United States, and Switzerland was more than a political makeshift suitable to the Italian situation; it was an ideal solution wherever the necessity for unity co-existed with powerful centrifugal forces. As early as 1848 he predicted the United States of Europe.

A publicist of great learning, literary talent and versatility, Cattaneo occupied himself with a wide variety of subjects—agriculture, administration, finance, education, literature—and made important contributions to many branches

of social theory. Most of his writings appeared as articles in reviews, *Annali universali di statistica* and *Il Politecnico*; the latter he founded and wrote for from 1839 to 1844 and from 1860 to 1863. It was through *Il Politecnico* that he hoped to accomplish the intellectual regeneration of the Italian people, to lead them away from romanticism and to prepare their minds for the scientific treatment of social problems. Cattaneo's wide range of interests appears in full light in his historical studies, such as *Notizie naturali e civili sulla Lombardia* (Milan 1844) and *La città considerata come principio ideale delle storiie italiane*, which he approached in a truly modern spirit, taking full account of geographical, anthropological and economic factors. As economist Cattaneo followed the liberal tradition; he decried the economic nationalism of Friedrich List and made a vigorous plea on logical grounds for the abolition of the civil decrees against the Jews. As he showed in *Ricerche economiche sulle interdizioni . . . agli Israeliti* (Milan 1836), these decrees, in excluding the Jews from the ownership of landed property, had encouraged them to become capitalists and usurers. In sociology, the problems of which he was one of the first to appreciate, Cattaneo's contributions were of the first order. He anticipated positivism in criminology, demonstrating the fallacy of the abstract conception of justice which considered only the crime and not the man, and pointing out that criminologists must seek instruction from anthropology; he stressed the linguistic and historical significance of dialects; finally, he did much to advance the study of social psychology which, as he attempted to show in a series of articles on what he called the psychology of associated minds, contains the secret of all civil history.

CATTLE INDUSTRY. See **LIVESTOCK INDUSTRY.**

CATTLE LOANS are of three main types, known as feeder loans, stocker loans and dairy loans. Feeder loans first attained importance when large herds were developed upon open ranges west of the Mississippi and marketed at the large meat packing centers. A profit could be made, particularly in the corn belt, by purchasing range cattle at the stockyards, putting them on good pasture or in feed lots for several months and reselling them at a premium as prime or finished cattle. Experienced lenders consider feeder loans a very desirable type of investment owing to the short maturities, the readily marketable character of the animals pledged and the rapidly increasing margin of safety provided by the gain in weight and quality.

Stocker loans, enabling cattlemen to buy more breeding stock or to defer the marketing of young stock, are needed for periods of six months to three years, but the notes are usually drawn for six to nine months and renewed. Experienced lenders view these loans when made on range cattle as less desirable than feeder loans, primarily because of the greater risk of price changes and losses from weather and disease. Stocker loans are safer when made to finance small herds in the intensive farming areas.

Dairy loans, to obtain dairy animals, are usually repaid in instalments from the sale of milk or milk products over a long period and therefore depend for liquidation largely upon the character of the borrower. This type of loan is particularly suitable to local lenders who know the capacity and integrity of the borrowers.

Local banks in, and north of, the tier of states extending from Ohio to Missouri have been able to provide funds for nearly all of their local cattle loans, but in other cattle raising states west and southwest the demand for loans greatly exceeds the supply of local funds. Legal limits on the size of loan to any one borrower restrict some banks with ample funds in making the larger loans. In consequence, there is a prevailing need for outside funds.

Local banks have sold a limited amount of cattle loans direct to their correspondent banks. Livestock commission companies, desirous of enlarging their own commission business, and cattle loan companies, designed to operate as middlemen between local banks or cattlemen and commercial banks largely to the eastward, have handled the bulk of such outside loans. Recently a number of agricultural credit corporations have been organized to obtain federal intermediate credit bank funds by rediscounting.

The Federal Reserve Banks and Federal Intermediate Credit Banks make no cattle loans directly but do provide very satisfactory rediscount facilities for such paper when properly drawn and satisfactorily secured. The Federal Reserve Banks may rediscount maturities not exceeding nine months for member banks; and the Federal Intermediate Credit Banks may rediscount maturities of not less than six months nor more than three years for banks, cattle loan companies, agricultural credit corporations and cooperative associations. The Federal Intermediate Credit Banks were designed, in part, to provide a large and dependable source of capital to finance cattle loans. Their holdings of such loans have increased steadily since their organization and at the end of 1929 exceeded \$24,000,000. The cattle loans held by the Federal Intermediate Credit Banks are but a small part of the total of such loans outstanding in the United States, but these banks are of considerable assistance in the regions most urgently in need of outside funds. Of the total cattle loans made by the Federal Intermediate Credit Banks during the years 1928 and 1929, approximately 55 percent were in the states of Texas and California, and approximately 85 percent in the states of Texas, California, Arizona, Nebraska, South Dakota and New Mexico.

The interest rate paid on cattle loans has, with relatively few exceptions, ranged in recent years from 7 to 9 percent. The lower rates apply to feeder loans and large stocker loans, both of which are most often sold to outsiders. The higher rates apply to the small stocker and dairy loans, which are most often held locally. The bulk of the cattle loans are being made at the rate of 7.5 or 8 percent.

There has been a high percentage of failures in the organizations handling cattle loans in every period of rapidly declining cattle prices or credit stringency. This is due largely to competition for a large volume of loans in an antecedent period of easy money and rising cattle

prices when rates of interest and margins of security asked of borrowers were reduced and when some loans were taken without any margin or inspection of security and borrowers were often urged to use more funds, especially for stocker purposes.

There has been no significant development of cooperative loans upon cattle in the United States. European cooperative credit loans such as those of the famed Raiffeisen societies are made largely to facilitate purchases of a few dairy animals, but this kind of financing is adequately provided for in the United States by the local banks. On the other hand, cooperative associations appear to be poorly adapted to financing the large and isolated herds of the American range country.

An economic program for cattle financing must include careful selection or supervision of the parties managing livestock, prudent lending in periods of rising prices, proper utilization of Federal Reserve Banks and Federal Intermediate Credit Banks and foresight as to changes in the cattle industry and the relation of such changes to changing credit conditions.

CAUCUS. This term is derived from American political jargon. Coined perhaps from an American Indian root meaning "to consult" (Algonkin *kaw-kaw-wus*) the word first appeared as the name of a cabal dominant in Boston politics during the last half century of the colonial period. While in its early usage it was widely bandied about and applied in a derogatory sense the term has come to cover various sorts of organized effort for party regularity. In the United States a caucus is a meeting by members of a party or faction for the purpose of choosing party leaders, formulating policy or naming candidates for public office. It is a meeting of a small group within a larger group: of voters in

local districts, of representatives in municipal, county and state legislatures or in Congress, or of a corresponding group in a non-political organization. "Caucus" in Great Britain refers to the standing organization of a political party. It came into general use in 1878 when misapplied by Lord Beaconsfield to the Liberal Association of Birmingham, but is now applied to controlling organizations of all parties. In Australia the term denotes especially groups of Labour members in federal and state parliaments, working in conjunction with trade councils to control the government; hence it has become an opposition name for the Labour party itself. Elsewhere, in New Zealand and France for example, it applies more generally to meetings of any legislative group.

As early as Washington's administration men of kindred spirit met to plan concerted action in Congress. In state legislatures party groups supplanted colonial *juntos* and revolutionary committees of safety. Beginning about 1790 meetings of partisans from both houses of the state legislatures nominated candidates for governor and lieutenant governor, and on some occasions proposed nominees for president of the United States. Nominations for president and vice president, however, soon came to be controlled by party groups at the seat of the federal government. Both Federalists and Republicans by secret caucus action drew up their respective tickets for the election of 1800, but with the decline in the number of Federalists in Congress thereafter, their caucus was no longer used for nominations. The so-called congressional caucus of the Republicans determined the tickets of Jefferson, Madison and Monroe.

This assumption of power was open to popular objection on several grounds. It was an extension of congressional influence to selection of the executive, while the constitution expressly debarred members of Congress from serving as presidential electors. Moreover, the caucus system was unfavorable to a candidate who, like Jackson, was weak in official support. Although in the beginning parties sprang from caucuses of the legislatures, with the extension of suffrage and democratic doctrine and with swifter communication there was a growing demand for more popular control of party organization. When the last congressional nominating caucus met in 1824 more than two thirds of the Republicans refused to attend, and its action in naming Crawford for president was without binding effect throughout the country. There-

after the delegate convention replaced the caucus in presidential nominations. Similarly methods of nominating state executives changed from purely legislative caucuses to mixed caucuses, complemented by outside delegates, then to "mongrel caucuses" or mixed conventions, in which legislators sat only in the absence of ad hoc delegates, and finally to conventions of delegates only. The adoption of the Seventeenth Amendment, which provided for the popular election of United States senators, removed the last extraneous function from the legislative caucus.

The maintenance of party regularity in the organization and business of the legislature became increasingly important, however, with the sharpening of party cleavage. Since 1824 this party control has occasionally been accomplished in Congress through joint caucus of Senate and House members, as in the case of the Republicans in July, 1866. But in general the caucuses of the two chambers act separately. Preliminary to a new Congress each party caucus in each chamber selects its chairman and secretary, chooses the party floor leader and agrees on candidates for president *pro tem* in the Senate and for speaker in the House, as well as for the other elective officers. Support of caucus nominees is a crucial test of party regularity. Since 1848 Senate committees, and since 1911 House committees, have regularly been selected in accordance with lists prepared by committees of the majority and minority caucuses. The work of these committees is subject to caucus supervision in principle and sometimes in detail. The majority caucus alone, however, determines the ratio of the strength of majority and minority parties on committees. In advance of congressional elections campaign committees, both senatorial and congressional, are created by the caucuses.

Of late party organizations in the individualistic Senate have refrained from binding decisions on legislative policy, employing the conference rather than the caucus form of meeting. House Republicans, after more than a decade of conference, restored the caucus in 1925. Those who enter are expected to be bound by the decisions of the majority, unless they express dissent and "bolt the caucus." House Democrats are bound by a two-thirds vote of their caucus, except with regard to constitutional construction, prior pledges to constituents or contrary instructions from a nominating authority.

Caucuses are voluntary associations unrecognized by rules save for permission to use the hall of the House for caucus meetings of its members. Their influence is therefore a variable factor in legislation. In a sharp clash of party principles or under the pressure of aggressive leaders, as during the period of Civil War and reconstruction, under Speaker Reed, and in the presidencies of Jefferson and of Wilson, party forces are welded for united action. But in times of personal responsibility and free union, when there is little attempt to marshal a permanent majority behind a party program, caucus discipline is rarely invoked.

CAUER, MINNA (1841-1922), German feminist. She was at first interested in historical research, devoting particular attention to the part played by women in social development, and was drawn into the ranks of the feminist movement almost against her will. As president of the Frauenwohl, founded in 1888 to revive the then quiescent German feminist movement, she ushered in a new and vigorous epoch in its history. Minna Cauer did not confine her interests to the narrower aspects of feminism. She used her influence to draw women of independent means into all phases of social reform. While the civil code was being revised during the nineties she carried on a vigorous campaign for the civil rights of women. In 1889 she assisted in founding the first trade union of women employed in mercantile enterprises. Her firm belief in the importance of the vote led her in the beginning of the twentieth century to concentrate her energies on woman suffrage. She was important in the founding of the *Welthund für Frauenstimmrecht* in 1904. As editor of *Die Frauenbewegung* from 1895 to 1919 her writings

set forth in a progressive spirit not only the problems of women but questions of social and political import. She was also the author of *Die Frau im 19. Jahrhundert* (Berlin 1898).

When the revolution of 1918 realized the ideals of social democracy (including the enfranchisement of women) for which she had fought, Minna Cauer, while welcoming the new era, found it impossible to participate in it politically. Her health had been seriously impaired by the persecutions which she had suffered as a supporter of the principles of international amity during the World War. It was to this cause and to that of education in the new era (through the *Bund Entschiedener Schulreformer*) that she devoted her remaining years.

ELSE LÜDERS

CAUWES, PAUL LOUIS (1843-1917), French juriconsult and economist. Associate in the law faculty of Nancy (1867-73) and paleographer for archives (1868), he was appointed in 1873 to the faculty of Paris, where he taught Roman law and the history of law. In 1895 he was appointed to the chair of political economy, which he occupied until his retirement in 1913. He became dean of the faculty in 1910. In 1900, in conjunction with Mahaim and Jay, he founded the *Association Internationale pour la Protection Légale des Travailleurs*, of which he was president until 1906. He was likewise founder and president of the *Société d'Économie Nationale*.

As jurist, historian and economist Cauwes drew his inspiration from the German historical school and the economic nationalism of List. At a time when economic liberalism in France was unchallenged except by the socialists, he asserted for the state the role of a factor in economic and social progress. He regarded the nation as an economic entity worthy of protection and preservation, and social well-being as the goal of the art of economics, which he conceived of as a necessary complement of scientific observation and theory. Thus he represents the reaction against individualism and liberal cosmopolitanism. Like List, Cauwes regarded protection as a safeguard of industry, a stimulus to production and a means for insuring the harmonious development of the economic state. He exerted a marked influence on French university economists, of whom very

few are today pure liberals, and he contributed largely to the progress of protectionism in France.

WILLIAM OUALID

CAVEAT EMPTOR, or let the buyer be on his guard, is a word of warning, a custom of trade and a rule of law. As the words go the purchaser must take his chance upon the title, identity, quantity and quality of the ware; he accepts the chattel for better or for worse. As practice has it the seller may be held responsible for title, he must make good a warranty and he is liable for fraud.

As maxim, custom and rule caveat emptor is a product of the Middle Ages. In days when a Christian economy had no rightful place for trade the affairs of the market place were beyond the law. One who engaged in trafficking did so at his own risk. After a time the casual character of exchange made the buyer's reliance upon his own acumen a matter of common sense. The articles were familiar; they were in plain sight; there was opportunity for inspection. If the traders were neighbors the merits and defects of horses, plows and seed corn were matters of common knowledge; if they were strangers the game of chance was to be won by the smarter. In friendly higgling the buyer needed no protection; in deals with the foreigner a safeguard would have robbed exchange of its incentive. Caveat emptor developed the mercantile virtues; it made buyers and sellers sharp, cautious and resourceful; it was "a good old doctrine for the encouragement of trade." Considerably later, when the profit motive came to be used to explain business activity, a rising laissez faire gave to the ancient precept a new sanction and a renewed support.

As trade became regular and business respectable the conditions which called caveat emptor into being disappeared. Wares were produced for the market; goods were passed along established routes by authorized dealers to regular customers. Articles were ordered from afar and contracts for their delivery were made in advance of their manufacture. Commodities of bulk were disposed of by sample; goods were used to produce other goods in a succession of

productive operations that could not be halted; a maze of negotiable paper marched along with the process of buying and selling. The multiplication of wares, the interlocking of industries, the impersonality of business relations and the long list of attributes which goods may possess all combined against the rule of thumb test of quality. A hurried commercial world could not wait until each individual had felt and smelled and probed; the goodness of the commodity was to be left to experts who could use scientific tests. A judgment could not wait for a meticulous determination of the exact verbal exchange between the parties in each particular sale; the trade had to have its rough measure of quality and its general understandings. A number of things had to be taken for granted or business could not have gone on.

The old custom of caveat emptor had to be bent to the newer ways of business. The bargain became the contract. The stranger with whom the buyer regularly dealt became a gentleman; his word was more and more to be trusted. It was not enough to win customers—they had to be held; it became good business for the seller to give a minimum warranty for his wares. The buyer might place future orders elsewhere; his option enabled him to demand that defects in purchases be made good. A longer period for inspection, a greater readiness to allow the return of goods and a disposition to adjust claims out of court came into vogue. The adage "the customer is always right" won a limited acceptance; a breath of life was breathed into the wall motto "satisfaction or your money back." The art of sharp dealing lost some of its repute and the cruder risks of a trade which had not yet found its channel disappeared.

In its turn the law made a belated adjustment to the necessities of a going business system. A court decides specific disputes between litigants; it is only as case follows case that it makes policies. The first change in caveat emptor was not in the principle but in its application. The buyer's right of recovery, once limited to fraud, was greatly enlarged by two devices invented by lawyers and eventually accepted by judges. One device was the rule of warranty. When the parties dealt at arm's length the seller could be held only for an express guaranty given at the time of sale; when goods were ordered in advance of manufacture an "implied warranty" was assumed as part of the bargain. The vagueness of the term made its use easy. The line between talk and promise could not be drawn with pre-

cision; as justice demanded—or judges willed—representations, labels and even advertisements came to have a standing in court. Once accepted as “evidence of warranty” it was easy to find an implied warranty within their words. The other device was negligence. The seller might be silent about obvious shortcomings; but from early times he was bound to reveal hidden defects of which he had knowledge. But the seller’s mind was not always an open book; it was necessary to presume on his part a certain detailed acquaintance with his property; and so to the words “he knew” it was easy to append “or ought to have known.” This catholic formula enabled the courts gradually to impose upon sellers higher standards of knowledge, care and accuracy in statement. Thus, without violence to the fundamental principle of caveat emptor, the contrivance of subordinate rules little by little enlarged the legal rights of the buyer. Yet a law differently applied is really not the same law. So courts came to “restate” the principal rule “to take account of the exceptions.” Legislation was evoked to remove outworn rules of law as well as to make secure the up to date holdings of the courts. In time a uniform sales act which contained a detailed code for the protection of the buyer was drafted and has been adopted by many state legislatures.

The response of law to business necessity has been slow and irregular. In England the older rule was relaxed much earlier than in the United States, where legal usage has proved to be much less adamant to change. In the United States the common law means one thing in one jurisdiction and a different thing in another; ancient and modern notions blend variously in the statutes of the several states; and even the uniform act, where it has been adopted, has not obliterated local habits of interpretation. Moreover, the buyer’s need to rely upon himself depends upon the market and the commodity. A setting of plymough rock eggs is legally bound to bring forth plymough rock chickens; but the dealer in works of art is obligated only to the best of his expert belief. Cotton is sold by sample; but the publisher of an encyclopaedia is not constrained to maintain the quality of the prospectus. A manufacturer may mix wrappers on two of his soaps without serious consequence; but a chemical house which allows a label of cough syrup to find its way on to a bottle of iodine may be mulcted in heavy damages. The buyer of stale bread in waxed paper may get his money back or claim a fresh loaf; the purchaser of imperfect raw

materials or defective machinery is entitled to redress for injury to plant and equipment. The courts may still be plagued with the case of the farmer who sows what it says on the package and reaps something else. A simple rule of law, with its clear cut exceptions, has encountered many commodities from many markets put to many uses—and has become an elaborate, changing and none too certain code.

An ideal picture of the buyer’s rights presents both a statement of tendencies and a standard by which existing practise is to be judged. The current confusion, which is passing, is at bottom a clash of ideas. An older theory makes the exact understanding between individual traders the standard of justice; a newer theory sets up as a test the minimum of goodness which a commodity must possess to be marketable. In courts of law, amid the confusion of rule and exception, procedure and precedent, the issue is uncertainly joined. But the trend is definitely away from the words which the parties said to each other and toward the understandings within the trades. The law is coming to regard warranty against obvious defects as implicit within the contract of sale, to look upon its expense as a necessary cost of production and to place liability upon that one of a succession of sellers who is financially responsible and easily reached. The law, in the holdings of the courts, is moving uncertainly toward a simple and definite code of obligations.

But his own vigilance and access to the law are not the buyer’s only safeguards. Both within business and by the state defenses against his own carelessness have been contrived. The pharmacists have set up standards of identity and of purity to which medicines must conform; trade associations have their tests of quality to which their members are committed; and the use of distinctive labels by manufacturers gives some assurance about the contents of packages and cans. The local authorities test milk before its sale; the states place their ban upon pest ridden commodities; the federal government draws a line between wholesome and unwholesome foods. The Federal Trade Commission, in a drive at unfair competition, tries to suppress the grosser forms of misrepresentation. The Bureau of Standards at Washington makes rigid tests of rival wares; their records might some day be opened to a public of purchasers. A rule of caveat emptor is made merciful, a right of resort to law is enlarged, an admission to the public market is denied inferior and injurious goods—

and a scheme of institutions for the buyer's protection begins to reveal its irregular outline.

In the flux of industrial change caveat emptor has not been lost. The ancient precept is still to be discovered behind the broadened rules of fraud, warranty and negligence, behind standards, inspection and trade practise. The protection accorded the buyer is still a narrow one. At best only a minimum of quality is assured, and that in matters that do not invite difference of opinion. Business is business and law is law, but neither insures quality to the book, long life to the garment, style to the furniture or durability to the automobile. In many industries improvement is directed rather to points of the product that can be talked up than to features in need of mending. At best the seller's words have a limited currency in court; salesmen are not limited to a simple recital of bare fact and salesmanship has not ceased to be a creative art. As yet the ordinary man cannot be certain that the article he was induced to purchase satisfies a need he really feels. The best warranty has a time limit; the reasonable man has the habit of allowing a valid claim to lapse through carelessness. The chicanery of petty trade is gone; the buyer may accept standard wares in the belief that he is getting his money's worth. But in plain speech and at law a refined caveat emptor still means that purchase is a game of chance.

CAVOUR, CAMILLO BENSO DI, CONTE (1810-61), Italian statesman. The younger son of a Piedmontese noble family, he became by study, travel and achievement a leading exponent of liberal nationalism. From Rousseau, Adam Smith, Bentham, Alfieri and other eighteenth century writers he acquired a dislike for absolutism and clericalism and an enthusiasm for personal and national freedom. From the example of the 1830 revolution in France he derived the conviction that constitutional monarchy is compatible with liberty. From sympathetic travel in England and association with

industrial capitalists and the classical economists he developed a fondness for English political institutions and economic policies. All these elements he fused in an ardent Italian patriotism.

As a wealthy private citizen Cavour did much between 1835 and 1848 to further scientific farming in Piedmont and to introduce the industrial revolution into northern Italy. In addition to managing large agricultural estates he became a captain of the new industry; he engaged in banking at Geneva and Turin, operated chemical factories, organized the Lago Maggiore steamboat company and built the first Italian railway. In 1847 he founded at Turin the famous newspaper *Il risorgimento*, which preached the national rehabilitation and unification of Italy. In 1848 he was largely instrumental in inducing King Charles Albert to establish middle class constitutional government in Piedmont.

As minister of agriculture, industry and commerce in the cabinet of King Victor Emmanuel of Piedmont after 1850, and as minister of finance and prime minister after 1851, Cavour labored to develop the economic resources of his country after English models. Classical political economy he held to be "the science of love of country." A convinced free trader, he secured the repeal of navigation acts and high tariffs and instituted a reformed system of direct taxes on incomes and inheritances.

As foreign minister after 1855 he showed consummate diplomatic skill not only in obtaining foreign aid for his program of Italian unification under Piedmontese leadership but also in overcoming domestic opposition and in harmonizing the conflicting currents of radical republicanism and reactionary clericalism with the liberal royalism which he championed. He had Piedmont, in union with France and England, go to war with Russia in 1855, and utilized the ensuing Congress of Paris (1856) to air Italian grievances against Austria. He arranged an alliance with France in 1858 and used it to wage the war of 1859 with Austria which resulted in the annexation of Lombardy and the duchies to Piedmont. He abetted Garibaldi in his spectacular conquest of the kingdom of the Two Sicilies in 1860 and cleverly intrigued so that that doughty republican surrendered his conquest to the king of Piedmont. Cavour had the satisfaction of proclaiming in 1861 the transformation of Piedmont into the constitutional kingdom of Italy; and although he died shortly afterwards he had clearly pointed the way by which Venetia and Rome would soon be incorporated in united

Italy. He did his best during his public career to convince Pope Pius IX that by surrendering Rome to Italy the papacy would gain in spiritual world esteem far more than it would lose in temporal Italian power; and Cavour's dictum of "a free church in a free state" provided the basis of the Law of Papal Guarantees in 1871 and of the Lateran Treaty of 1929.

CELIBACY is the unmarried state. A lone negative describes an uncertain institution; a departure from customary usage has no set form. A child is not a celibate, and yet no fixed count of years is a prerequisite. An aged person, recently bereaved, can never know the condition; the word is dubiously applied to the widowed living with their families. A deliberate acceptance is not a distinguishing mark; celibacy may be achieved by free will, by accident or by compulsion; it is a voluntary order and a residual estate. It betokens continence, but does not of necessity imply it; the ascetic, the irregularly attached and the prostitute may in common lack the marriage bond. Its way may be solitary or communal; it is alike a private plan of life and an established discipline. As conditions are unlike, cultures differ, forms of marriage vary and its arrangements change, celibacy presents a like variety. A countless number of celibates, scattered through centuries and across continents, make up a heterogeneous group.

In society at large celibacy is an evasive institution. Among savages its fortuitous existence has little formal recognition. The sex urge is accepted as natural and a sanctioned union as the destiny of every child. If it is not attained the fault lies with the usages of marriage within the tribe. A custom which forbids a woman to precede her older sister into wedlock may cause both to go unmarried; a right which gives to elders the first claim to women may cause the

young bucks to wait for mates long overdue. Tribal usage may make a place for surplus women either by sanctioning concubinage or by introducing polygamy, which, although never general, may be allowed to those who can bear it. At times infanticide may be a precaution against an excess of females. A group of the unattached may be set apart for religious observance. Almost universally the marriage bond is merged with other relationships; even where the matriarchate prevails in form wives may be personal property; often laborers for the fields come by way of marriage. Almost everywhere an imperfect definition of marital arrangements, an ease in the putting away of mates and a certain tolerance of irregularity confuse the line between the celibate and the marital estates.

Among hand cultured peoples celibacy claims an incidental toll of the operation of the marital institution. In China, where ancestor worship demands progeny, it is a curse whose cause is poverty. In India, where a human life must unfold, it is the ascetic state preceding marriage and the hermit life after its joys have been taken—or else an incidence of a caste system. In the Moslem world, where devotion does not deny the flesh, it is the visitation of Allah upon the demented and the deformed, the unfortunate and the unfit. As a voluntary condition it exists only in an occasional holy order. In the world of tool and craft, among the Incas and Athenians, in the Egyptian city and Chinese village, celibates are human bits outside the marriage system or persons consecrated to holy work. They are almost beyond the social pale or else they walk with gods.

It is communion with the gods which first gives to celibacy a distinct form. Priestly abstinence from marriage rests upon contagious magic. Like calls forth like; an offering of virginity appeases the gods of fertility. Among many peoples, the Aztecs for example, a sacrifice of maidens insures an abundant harvest; among others—the Romans are a case—a cult of vestal virgins gives a magical efficacy to a sacred rite. In like manner, where the office does not belong to a caste, here and there an order of unmarried priests appears. Its ranks may be made up of volunteers or conscripts; the initiates may be denied formal marriage, dedicated to perpetual celibacy or suffer a loss of vital organs. Strict continence may be enjoined or ceremonial indulgence allowed; many temples have their hordes of sacred prostitutes; cults of male har-

veil made of nuns brides of Christ. Today the suggestive talkie and the magazine of confession are a sap to unsatisfied sex appetite. It remains to be seen whether a passion denied its proper outlet can be sublimated in the varied round of contemporary activities. An escape from continence entails a clash of values. The technique of birth control divorces love life from procreation; as a result the sex union ceases to be affected with a public interest. The city, not so curious about private life, relaxes the discipline which the neighborhood exercises over its members. An unsanctioned union, known as the companionate, takes from celibacy its greatest deprivation. For the individuals, all things considered, departure may be "the better part"; but it has offsetting costs in conduct which runs counter to an established code and in a failure to avow an intimate relationship.

At present secular celibacy is far from established. It rests upon a cultural fault line between modern circumstance and mediaeval idea; it is peculiarly dependent upon the future of matrimony. The urge toward mating has been too strong to be pent up completely within so elementary a formula as Christian marriage; the state has in divorce provided an escape from irksome unions. At present the very conditions which are keeping men and women out of wedlock are making for a revision of marital arrangements. The declining value of ancestral name, the economic independence of women, the divorce of industry from the family, the disentangling of sex life from reproduction—all these are disturbing the balance between social and individual values in Christian marriage. Since men and women differ in their urges and their preferences a comfortable celibacy which can bring marriage to terms will continue to claim its votaries. But as an ancient institution responds to modern necessity it will still attract many unwilling to take the sterner chances. The spreading domain of celibacy is not to lose its character; it is to remain a voluntary order for the elect, a condition of waiting for the hopeful and a residual estate for the unfortunate.

CELTIC LAW. See LAW.

CEMENT is a term used in a rather broad sense colloquially and technically, but it is restricted in engineering to the hydraulic cements which possess the property of hardening under water. All of these, however made, are composed chiefly either of lime silicates or lime aluminates or of both. The principal among these is Portland cement, an artificial product invented about 1818 in France and now made in large quantities in many countries.

Of all the hydraulic cements now known only one, puzzolan cement, was ever used during ancient or mediaeval times. Ancient masonry constructions in all countries were made either of brick or rough stone, set commonly in lime mortar, or were, as the great cathedrals, constructed of cut stone held in place merely by its weight and the perfection of the cut surfaces. Only in ancient Rome was the use of puzzolan cements established; these were made by mixing slaked lime with volcanic ash or *pozzuolana*. The industry still exists on the flanks of Vesuvius.

Many Roman bridges, aqueducts and roads and some great Roman buildings employed puzzolan cement. But over western Europe lack of known local raw materials prevented its use, and during the Middle Ages hydraulic cements were practically unknown and unused. Toward the end of the seventeenth century the epoch of fortress construction led to interest in more resistant mortars than ordinary lime, and products were discovered which gave results closely resembling the Roman *pozzuolana*. About 1800, when canal and highway construction was coming into prominence, French and English engineers and chemists were actively searching for deposits of naturally impure limestones, which when burned and ground would yield good hydraulic products. In the United States

similar search, stimulated in every instance by the immediate necessities of some local canal construction, led to the discovery and development between 1818 and 1840 of natural cement districts such as the Rosendale and Buffalo fields in New York, the Lehigh region in Pennsylvania, the Cumberland and James River districts of Maryland and Virginia. Their development led to the growth of the natural cement industry, which for many years supplied cement primarily for public works, bridges, railways and fortifications. It continued to expand until it attained its maximum output of almost ten million barrels in 1899. By this time the natural cement had come into sharp competition with the newer growing Portland cement industry, and in the following year the production of Portland cement for the first time exceeded that of natural cement. Thereafter the natural cement industry, failing to take advantage of modern technology, gradually declined and became unimportant in the United States and in every other leading industrial country except France.

A few decades after natural cement came into use in Europe, Portland cement was invented almost simultaneously by Vicat in France in 1818 and by Aspdin in England in 1824. This industry did not start in the United States until 1785. Portland cement manufacture consists in making a synthetic chemical product from rather simple raw materials—limestone and clay—by the free use of heat and mechanical grinding. The greater strength and uniformity of Portland cement gave it technical advantages over the older naturals and its industrial life coincides with the great eras of railway expansion, of port and dock improvements, of concrete steel building construction and of modern highways. In 1930 its three leading uses in the United States in order of importance were: for concrete for roads and streets; for structural concrete for commercial, industrial, public and private buildings; and for various farm purposes. It furnishes the mass of all our modern construction and is intimately allied to all recent progress in transportation systems, housing developments and manufacturing plants.

During the last century cement has been associated definitely with, and has indeed in some periods conditioned, the development of the varying stages of industrial and social progress. Neither the growth of large cities nor the spread of modern transportation systems would have been easily possible without the use of a strong construction material cheaply made

and easily transported and laid. Together with steel and glass, cement has made possible the creation of a new and distinctive type of architecture.

The spread of industrial civilization into less developed countries has been accompanied, and in fact in most cases preceded, by the use of cement. This process has generally involved the construction of port works, of rail or highway lines, of mine or mill buildings and eventually of city office or dwelling construction. In all these stages cement has been of fundamental importance. The first cement so used in the less industrialized countries has been generally imported from one of the older areas; for the manufacture of cement, even in a relatively small unit, requires large capital, steady operation and abundant fuel supply. So also the inception of the cement industry in such countries is directly a function of the introduction of foreign capital and construction works. When a country has promised industrial development, cement manufacture has been taken up locally, often by those responsible for the original port, railway or dam constructions, provided of course that suitable raw materials, including fuels, are easily available. In a number of instances cement companies in the leading cement producing nations of the world have established plants of their own in industrially backward countries.

The Portland cement industry has been characterized by very rapid development. The rate of this growth in the United States is indicated in the following table:

PORTLAND CEMENT OUTPUT IN THE UNITED STATES,
1880-1927

YEAR	QUANTITY (BARRELS)
1880	42,000
1890	335,500
1900	8,482,020
1910	76,549,951
1920	100,023,245
1927	173,206,513

Source: United States, Bureau of Mines, *Mineral Resources of the United States*, pt. II, *Non Metals*, for 1924, p. 358-59, for 1927, p. 273.

The world's production of cement, chiefly Portland cement, reached in 1930 the total of some sixty-five million tons annually. Of this the United States makes about thirty million tons, a little less than half the world total. Germany follows with some seven millions, France comes next with over five, and the United Kingdom is fourth with just under five

millions. There are no close competitors to these four nations; Japan, Italy and Belgium are the nearest, with about two and one half million tons each. Some thirty-five other countries combined make up the remaining ten million tons. This summary brings out strikingly the close relationship between the general industrial status of a country and the development of its cement industry.

The problem of international trade in cement is concerned with other factors than output, since it is based primarily on price competition. Export shipment of cement normally involves cheap fuel, cheap labor and cheap transport to a much greater degree than in the case of products of greater specific value. Of these three items the term fuel commonly means coal; other fuels are in local use but do not affect the export markets to any appreciable extent. The labor in cement mills is chiefly unskilled and in most countries is not unionized; the term "cheap labor" may imply low wages per hour or a low wage cost per ton. Cheap transport implies in most cases water transport and the importation of some bulk staple in constant demand needed by the cement exporting country. Finally, the creation of a steady export trade in cement implies surplus production, due to present or earlier supplies of cheap capital in combination with the factors noted above.

In view of these conditions it can easily be understood that despite its vast production the United States normally exports little cement, a mere unimportant fraction of its total output at most, and that Great Britain and Germany export steadily on a larger scale, varying chiefly with their own current trade conditions. France, in spite of a large output, exports little. Belgium, with a far smaller output than any of those so far named, exports constantly and in large amounts. In this last case all the export requirements are met: excess capacity, cheap capital, cheap fuel, modern equipment, low wages and cheap transport. The export tonnage is directed of course toward whatever country or region offers the best current market; any serious disparity in wage or prosperity level suffices to create a temporary and perhaps permanent flow.

The organization of the cement industry in any country depends on two unrelated sets of factors, one technical and the other legal. In the first group we have the simple facts that cement raw materials are widely distributed naturally, that their deposits have of themselves no great money value, that the product is sold at a low

price per ton (averaging only about ten dollars as against twenty for pig iron) so that transport charges weigh heavily. All these factors tend to prevent the formation of great cement centers such as are common in the iron trade. It is normally cheaper to make cement near its best markets; and it is commonly easy to find good raw materials near them. Thus in place of a few great mills owned by a few great companies, as in the steel industry of most countries, we find the cement industry commonly represented by a very large number of relatively small mills and scattered widely over the national territories. The thirty million tons output of the United States, for example, is made by over one hundred sixty mills owned by at least eighty separate corporations. Similar conditions as to the number of mills and comparatively small average size of the individual operation exist in other countries; the maximum of dispersion and division is to be found in France.

The number of controlling corporations is of course a different matter, since it is influenced largely by the varying legal policies of different countries. But regardless of laws the incentives to intensive integration in the cement industry are relatively small, since an industry with widely scattered units offers little economic saving if placed under single control. Aside from the underwriting and speculative profits of a flotation there are few strong reasons for buying mills which must always remain geographically far apart.

In countries such as Germany and Belgium, where cooperative sales agencies or cartels are legal, they are the means usually adopted to secure price control by otherwise separate manufacturing units. The cartels seem in each case to have had fair control over export prices and tonnages for most of the post-war period. This has been due less to the strength of the cartel idea itself than to the fact that both Germany and Belgium have been shipping into prosperous markets. With a product whose raw materials are so common as those for making cement it is obvious that even a brief period of successful marketing induces the building of new mills to share in the profits of the cartel. In any period of declining prices abroad the export cartel fails to function and the stronger companies withdraw to act independently.

In Germany practically all the cement manufacturers of any importance belong to three large cement associations, among whom the country is divided. These associations attend to matters

concerning limiting sales, apportioning government orders and supplying raw materials. Over the associations is the Deutscher Zement Bund, which in conjunction with the national commissary for cement fixes prices in each of the three association territories, issues export permits and settles questions arising between the associations. There are also four German cement associations which carry on technical research, test members' output to insure conformity to scientific standards, disseminate information to members and forward the general interests of the trade.

In Great Britain and Canada, where cartels are illegal or extralegal but monopoly through direct ownership is legal, the cement industry in each instance has fallen almost entirely into the hands of one large corporation. The corporations which control the bulk of the national cement output in each of these countries have succeeded in holding interior prices at relatively high levels. This has necessitated in each case buying out threatened competition, a process which cannot be continued indefinitely, but which has so far assured the commercial and stock market success of the combinations involved. In Great Britain over 75 percent of the Portland cement output is controlled by the Associated Portland Cement Manufacturers, Ltd. This organization and the British Portland Cement Manufacturers, Ltd., which it dominates, are amalgamations of a large number of previously independent companies. This combine was begun before the World War. Another organization, the Cement Makers' Federation, including in its membership the manufacturers of about 90 percent of cement made in the United Kingdom, deals with labor questions, fixes minimum prices of cement to be sold by its members within the British Isles and regulates retail prices through a rebate system. Another interesting feature of the British industry is that a number of cement plants are owned in whole or in part by coal companies. This is due to the tremendous quantities of fuel which are needed for cement production.

In the United States, where neither price agreements nor monopolies are held legal, the actual status of the cement industry is less clear. Local cooperative sales agencies or organizations were common enough during the growth of the natural cement industry, but with the later period of public interest in trusts such methods became inadvisable as well as illegal. The development of the American Portland cement

industry has taken place, therefore, during a period of uncertainty with regard to the feasibility of price control by agreement or direct ownership. At the outset this was relatively unimportant, for from the inception of the industry up to the panic of 1907 there had been little necessity for overcompetition between American Portland cement companies. During these thirty years it had indeed been chiefly a question of building mills fast enough to supply a steadily growing demand at good prices. But the overpromotion of mills during the years 1905-07 led to overcompetition when they all came into operation on a badly depressed post-panic market. From 1907 to about 1915 price wars and bankruptcies were fairly common in the cement industry, interrupted spasmodically by local and illegal attempts at price control. One attempt in 1906-08 of somewhat broader outlook than the average was carried on under shelter of a group of patents. It failed chiefly because the attempt to control prices was mixed with a more individual attempt to make money out of the patents. At its height the association controlling the patents represented 70 percent of the United States Portland cement industry.

In 1908 the industry was dominated by nine separate groups of companies. Some combined plants in one region; others controlled them in several market areas. Groupings of these sorts have continued, although there have been some changes. Since the World War most of the larger companies have acquired plants in more than one section of the country in order to increase the areas over which they could profitably market their products. In 1930 the four largest companies together had about one third of the entire national capacity; the United States Steel Corporation alone controlled a sixth to a fifth of the national production. The steel corporation has produced cement as a by-product from slag since the beginning of the century, and its own cement producing subsidiary has grown up to second or third rank. In 1930 it acquired what was previously the largest cement company in the country, thereby somewhat increasing its market area. In this step it may have felt or visualized the competition between cement and steel.

Trade associations have also played an outstanding part in the organization of the United States Portland cement industry. The Portland Cement Association, whose membership produces over 90 percent of the Portland cement output of the country, has had as its main functions since its inception in 1903 the increase of

the sales and the improvement of the quality of cement. The Cement Manufacturers' Protective Association, organized in 1916, has carried on many of the activities of an open price or open competition trade association. It has gathered from its members and disseminated among them information concerning "specific job contracts" for future deliveries of cement to avoid spurious orders and the breaking of contracts, information as to "specific job contract" prices, credits, freight rates on cement, production, stocks of cement and clinker on hand, and shipments. It is uncertain to what extent these associations have influenced production and prices. In 1924, however, the United States Supreme Court held [268 U. S. 588] that the activities of the latter did not constitute unlawful restraints upon commerce. Various cement associations in conjunction with engineering societies and the federal government have been responsible for the establishment of standards in the industry.

Since 1915 production has ranged from 52 to 85 percent of the total productive capacity of the Portland cement mills of the country. During these years there has been little competition in price or quality, a "standard" Portland having been supplied in quantities never in excess of the current market requirements. This is possible, of course, only if the producers exercise proper self-restraint, since there are no legal methods of enforcing cooperation along these lines in the United States. During the past few years, however, there has been the beginning of manufacture of cements of better than "standard" grade at somewhat higher than standard prices.

The Portland cement industry is on the whole highly mechanized. In the United States it uses more than half again as much horse power per wage earner as the combined iron and steel industries. As a result the great majority of its 36,322 wage earners in this country are unskilled. All but a few of them are males. Most of them work in an atmosphere filled with cement dust. While this does not produce any of the sensationally fatal results found in most of the other dusty trades, it affects the upper respiratory system and furnishes an extremely unpleasant working environment. The digestive systems of cement workers are also affected adversely, and an unusually high percentage of the workers are troubled by deafness and skin diseases. The rate of two-day and longer absences among cement workers is much greater than in most other industries.

The hours of American cement workers average about sixty-one per week. The two-shift system of eleven or twelve hours seven days a week (seventy-seven or eighty-four hours a week) exists in about half the Portland cement plants of the country in such departments as the raw and clinker grinding and coal mill departments, where technological considerations require continuous operation. A considerable number of plants, however, have since the World War changed in these departments, where the heat is generally extremely great, to a three-shift system of eight hours, seven days a week (fifty-six hours per week). But plants still exist in which the night shift works ninety-four and one half hours a week in these departments. Nevertheless, the hours of most of the workers in the quarry and packing and some intermediary departments, comprising almost two thirds of the cement workers, are not as excessive as in the continuous operation departments. The plight of American cement workers has been accentuated by the almost entire lack of trade union organization among them.

CENSORSHIP is the policy of restricting the public expression of ideas, opinions, conceptions and impulses which have or are believed to have the capacity to undermine the governing authority or the social and moral order which that authority considers itself bound to protect. Censorship is sometimes confused with tabu, but the distinction between the two concepts is clear, although their relations within the

social process are close. Censorship is a conscious policy; it may be enforced without the assent of the greater part of society. A tabu enters intimately into the scheme of feelings of those who entertain it. The tabu is particularly effective in self-control; when it is applied by group action to those who do not entertain it, such action is generally spontaneous and unreflective. Censorship may, however, set out from tabu as a premise of action. The horror of blasphemy is of the nature of a tabu; censorship may repress blasphemy as inimical to a smoothly operating social order. If the tabu against blasphemy disappeared censorship would no longer concern itself with its suppression.

Censorship may be exercised by the political or by the religious authorities, or even by private persons who take upon themselves a quasi-official position in respect of the enforcement of accepted censorship policies. The censorship of political expression has generally been a function of the political authorities; that of religious expression has been a function of the church; while moral censorship has involved not only the combined activities of state and church but also the active participation of private persons. But in this realm it is unsafe to draw hard and fast distinctions. There is a natural tendency in any form of censorship to identify its interests with those of other forms. The animus of the traditional minded Athenians against the teachings of Socrates may have been primarily religious, but moral and political motives were skilfully woven in. The censorship in czarist Russia was primarily aimed at the suppression of subversive political ideas, but the autocracy was solicitous about identifying its interests with those of the church and of sound morality; the "Little Father" was a symbol of orderly and loyal family life. In the western censorship of Bolshevik communications a systematic and on the whole successful effort has been made to identify the political subversiveness of Bolshevism with irreligion and immorality.

The most important applications of censorship have been to the spoken or written word; to action as represented in the theater, pantomime and dance; and to the plastic arts. Censorship of attire, as at public bathing beaches and on the stage, has assumed importance only in the last half century.

The scope and methods of censorship vary according to the social order it seeks to defend and the nature of the attack. When a religion

is predominant and under fire, blasphemy and heterodoxy are prohibited. When the state is in the ascendant, treason is suppressed. When the industrial order is firmly established, "radicalism" may be a favorite object of censorship.

In classical antiquity censorship appears to have been applied only sporadically. Sparta placed a ban on the forms of poetry, music and dancing current in the fifth century B.C. on the ground that they induced licentiousness and effeminacy. Aeschylus, Euripides and Aristophanes suffered under a censorship because of their too free thought on religious matters. In republican Rome the theater was banned by the censor, except on the occasion of certain games, where a time honored tradition of license in speech and gesture gave a limited degree of freedom to dramatic art. No permanent theater was permitted in Rome before the time of Augustus. There is no clear evidence of a censorship of books either in Greece or Rome. The poet Ovid was indeed banished to the shores of the Black Sea by Augustus, and it has often been asserted that the grounds for his banishment lay in his licentious poems. But the poet himself points out (*Tristia*) that other poets were circulating with impunity even more licentious verses. In the first century A.D. the Roman political writer had to be on his guard against the hostile attention of the tyrant, and according to Tacitus free expression of opinion on matters of current history virtually disappeared.

The earliest and most sweeping censorship of the Christian church is probably that contained in the Apostolic Constitutions, which purport to have been written by St. Clement of Rome at the dictation of the Apostles. These constitutions forbid Christians to read any books of the Gentiles, "since the Scriptures should suffice for the believer." This general prohibition of St. Clement (*circa* 95 A.D.) was followed by a long series of prohibitions issued by the early church fathers. In 325 edicts were issued by the Emperor Constantine and prohibitions by the Council of Nicaea against the writings of Arius and Porphyry. The emperor prescribed the death penalty for anyone who might conceal copies of the forbidden works. In 399 the Council of Alexandria, presided over by Bishop Theophilus, issued a decree forbidding the owning or reading of the books of Origen. The Egyptian monks protested and the bishops were obliged to call in the prefects to enforce the edicts. In 446 Pope Leo I ordered

the destruction of a long series of writings described as out of accord with the teachings of the synods of Nicaea and, therefore, antagonistic to the Christian religion, and added further, "whoever owns or reads these books is to suffer extreme punishment." In 499 Pope Gelasius issued what was later referred to as the first papal index. It presents a catalogue of books prohibited, but the prohibitions regard not private or general but public or official reading.

Writers during the Middle Ages submitted their manuscripts to their superiors as a matter of courtesy and as a precaution against later censure. When the rise of printing and the growth of culture increased the numbers of authors, ecclesiastical authority demanded formal censorship. In 1501 Pope Alexander VI issued a bull against unlicensed printing and thus introduced the principle of censorship in this sphere. This policy, directed exclusively against books, was intended to protect the church against heresy and was accepted by all countries under the jurisdiction of the church of Rome. The Scottish Estates in 1551 prohibited all printing of every description unless previewed by authorized persons. In England the privilege of printing was confined to the Stationers' Company, which was chartered in 1556. The code of 1586 restricted printing in England to London, Oxford and Cambridge, limited the number of printers and ordered all books to be read, previous to publication, by the Archbishop of Canterbury or the Bishop of London. In 1690 Richard Pierce printed *Publick Occurrences* in Boston for Benjamin Harris. The legislative authorities promptly forbade further printing without license.

Until religious drama began to be obsolete in England, the stage was controlled and censored by the church; since then the Master of Revels, the Privy Council, the Star Chamber and the lord chamberlain have been successively in charge of the censoring of plays. The lord chamberlain was active by 1628, and he received statutory authorization in 1727. It was Jeremy Collier who in 1698 by his *Short View of the Immorality and Profaneness of the English Stage* firmly established the censorship principle.

Censorship may take the form of an examination of material in advance of publication and its suppression if disapproved. This is known as preventive censorship, in contrast to punitive censorship, which inflicts penalties after the offense and seeks to destroy the offend-

ing material. The censorship of antiquity was punitive, while that of the mediaeval church and of early modern times was in general preventive.

In 1693 the government of England formally abandoned the preventive censorship of printing and began the punitive. No one was to be prohibited from publishing anything, but he must run the gauntlet of possible prosecution for slander, sedition, immorality and blasphemy. Blackstone states that "the liberty of the press . . . consists in laying no previous restraints upon publications and not in freedom from censure for criminal matter when published." The amount of substantive freedom obviously depended upon the current conception of criminal matter.

Preventive censorship has been kept alive in England for the control of the stage. In France it has played a considerable part in the handling of political material. All cable messages from Soviet Russia must be passed by the censor; preventive censorship has been freely applied to dispatches from Fascist Italy. Even where there is no officially acknowledged censorship on material sent abroad a foreign correspondent often finds it expedient to submit his dispatches to the foreign office for approval, lest he be denied access later to important sources of information. In America powerful religious and business organizations sometimes exercise what is virtually a preventive censorship over the press. In general, however, the volume of material coming to the printing presses has become too vast to be examined by any censorship in advance of publication. Any practicable censorship must be punitive, except in times of war, when the necessity of depriving the enemy of sources of information demands a huge expansion of censorship personnel.

While political censorship has played an important part throughout modern times, especially in periods of great political upheaval, the dominant concern of censorship has been the suppression of material and activities presumed to have a degrading effect upon public morals. This preoccupation of the censor with problems of sexual morals has as a rule appeared simultaneously with the rise of the middle class to political dominance. Autocratic and aristocratic governments have seldom applied censorship to such matters as licentious books, pictures or plays. Neither does it appear that the one existing example of a proletarian government, Soviet Russia, takes this issue very seriously. A plausible explanation lies in the fact that the middle

class position can be maintained through generations only by thrift, prudence and self-control—virtues that are believed to be seriously shaken by licentious communications. In England, France, the Netherlands and Germany the antagonism of the middle class to aristocratic licentiousness exhibited itself in diatribe and sermon long before the bourgeoisie attained a position of political dominance.

Censorship of morals in the late eighteenth and early nineteenth century lacked any definite statutory basis. In any specific case the police might intervene in the interest of public order. Obscene publication or exhibition was early a crime under American common law, and statutes dealing with the matter were enacted in Vermont in 1821, Connecticut in 1834, Massachusetts in 1835. In England the principle of censorship was definitely established in 1857 by Lord Campbell's Act, under which a magistrate or the chief of police might issue a search warrant upon presentation of an affidavit that obscene publications were being sold or held for sale in certain premises. In 1868 a decision by Lord Chief Justice Cockburn gave a clearer degree of definiteness to the crime of obscene libel. A Society for the Suppression of Vice had been organized in 1802, and for a time exhibited considerable activity in bringing pornographic literature to the attention of the police. A vastly more active society was organized in New York in 1873 under the leadership of Anthony Comstock. This society was chartered under a special act of the New York legislature; its agents were given rights of search, seizure and arrest. Within a few years similar societies were organized in other states; of these the New England Watch and Ward Society won the widest public attention.

Under an act of 1873 the Post Office may refuse to transmit through the mails matter which it pronounces obscene. The Tariff Act of 1842 prohibited the admission of obscene books through the custom house; similar provisions have been incorporated in later tariff acts, including that of 1930.

The obscene picture, book or spectacle, pornographic in character and intent, is generally considered as open to legitimate censorship. But any administrative description of such matter which is definite enough to guide the action of police officers will at the same time apply to works of art, often of great genius and vital moral worth. The moral censorship through the nineteenth and twentieth centuries has been

notable for the prosecution of famous works of art, such as Flaubert's *Madame Bovary* and Hardy's *Tess of the d'Urbervilles*. In America under one jurisdiction or another many books of outstanding literary merit have been subject to censorship. So universal has been the stupidity of censorship in dealing with works of art that even many of those who believe in the importance of suppressing pornography have come to view censorship as on the whole an undesirable institution.

Often more effective results are secured by relying upon a "voluntary" censorship than by depending upon a compulsory one. Usually the "voluntary" arrangements have been perfected in the hope of averting greater interferences. The newspapers of the United States, England and several other countries organized "voluntary" censorships during the Great War. The moving picture industry and the stage have imposed restrictions upon themselves. The National Board of Moving Picture Censors was accepted by the producers, and they also took into association with them an official who was supposed to standardize productions in such a manner as to lessen the vulnerability of the enterprise to regulative attacks. Libraries and booksellers have sometimes undertaken to censor books, declaring that they would not circulate books "personally scandalous, libellous, immoral, or otherwise disagreeable," and endeavoring to secure the cooperation of publishers. Private groups have often sought to intimidate the producers, distributors and the public; such has been the technique of the vice leagues, the Ku Klux Klan and many pressure organizations. The Daughters of the American Revolution and various industrial, racial and religious groups have "blacklisted" speakers and protested against cartoons, headlines, editorials, posters, plays and books which reflected against their organizations. There have been "letters to the editor" or manager, delegations of protest and withdrawal of financial support. Preachers, teachers, editors, reporters and members of all the articulate trades and professions have been targets for everything from simple criticism to instigated violence.

In general it may be said that censorship technique demands that censorship shall be applied as unobtrusively as possible. The German authorities would not permit their newspapers to appear with the blank spaces which so often marred the French press, or with the inked columns which were once so common in

Russia. Codes of practise have been developed to facilitate the administration of censorship regulations; the official rules of censorship for the German press, published in 1917, went into profuse detail in prescribing rules for the elimination of anything detrimental to morale.

Every censorship produces a technique of evasion as well as a technique of administration. The Petrograd *Dien* (Day) was suppressed by the Communists, and immediately reappeared as *Notch* (Night). Clemenceau circumvented the order suspending his paper, *L'homme libre*, by rechristening it *L'homme enchaîné*. *La lune* was suppressed by the censor and passed into *L'éclipse*. In the continuous matching of wits the purveyors of dangerous material often came out ahead. A radical democratic paper in Germany had much trouble with the authorities during the war. On the anniversary of Bismarck's birthday it came out with a huge headline, "Bismarck's Greatest Day," and was passed by the censor. The article said that his greatest day was when he urged a peace of moderation against Austria and created an important precedent for the rulers of Germany.

Great skill and ingenuity have been lavished on the secret printing and distributing of journals banned by the censor. A Russian printing office in London published the *Bell* and it is reported that Alexander II was an assiduous reader of the paper. The successive waves of ecclesiastical and political persecutions in France led to the growth of a large clandestine press both inside the country and in Holland. The "gazettes of Holland" were famous in the eighteenth century and later. During the war *La libre Belgique* was remarkably successful in eluding authority. In 1890 the German Index Expurgatorius contained the names of a hundred and forty-three German newspapers and foreign journals and periodicals of socialist tendency, and a huge smuggling system arose for the transporting of socialist literature into Germany.

It is universally conceded that the censorship which draws publicity to an "evil" thought is a clumsy censorship, and that obstruction should be imposed near the source. Moreover, it is a notorious fact that censorship or the threat of censorship may make the fortune of a book or play which might otherwise have failed to win public attention. Various authors, publishers and theatrical producers have been popularly charged with deliberately presenting their work in a form to challenge the attention of the

censor and to win the *réclame* of a prosecution.

It is a moot question whether censorship can actually attain important ends in the complicated circumstances of modern life. The military censorship during a war, supported as it is by universal patriotic fervor, may succeed in depriving the enemy of much miscellaneous information that might be useful and in protecting the civil population against the discouragement that would follow upon an exact account of national weakness and enemy strength. Political censorship, as in czarist Russia, may for a long time force reform movements underground. The resultant security of the established order may, however, be wholly deceptive. By suppressing reform the censorship may transform it into a revolution.

Similarly the apparent victories of censorship in the field of morals are likely to prove vain in the long run. New opinions in morals may yield to transient restraint, only to plunge forward resistlessly. What appeared daring and deserving of censorship in one decade becomes commonplace in the next. It does not follow that censorship is necessarily doomed to failure; but it is evident that the problem is more difficult, and the technique required more subtle, than believers in censorship will admit.

CENSUS. In the modern sense of the term a census is primarily an official enumeration through direct visitation of all the people either physically present or regularly residing in a country or in any of its subordinate divisions. An enumeration of all persons physically present is a *de facto* census; one confined to residents, like the census of the United States and its subdivisions, is a *de jure* census. A natural extension of the enumeration makes it include the collection of various data concerning the persons enumerated, such as race, sex, age, marital condition, etc. By extension in another direction the unit observed has been changed from one person to one farm, resulting in a census of agriculture, or to one manufacturing establishment, resulting in a census of manufactures.

The term census is borrowed from a Roman institution of a quite different character. The Roman census was a register of adult male citizens and their property for purposes of taxation, the distribution of military obligations and the determination of political status. This register, although subject to periodic revision, was essentially continuous, unlike the modern census which attempts a complete enumeration at a particular point of time and has no direct relation to any previous enumeration.

A census, being a sort of photographic record of a population group at a given moment, resembles a periodic taking account of stock in a business. Such an account needs to be supplemented and checked by a record of transactions during a period of time, usually a year. The scientific importance of a census lies in large part in the fact that it furnishes the needed basis for a study of changes in the number of people through births and deaths, immigration and emigration, and of changes in their status through marriage and divorce.

Scientific interest in the application of the numerical method to the study of population groups seems to have been undeveloped in the ancient world. The main roots of population statistics hardly run back beyond the second half of the seventeenth century. In 1661 G. B. Riccioli published in Italy his *Geographiae et hydrographiae reformatae libri duodecim* and in 1662 John Graunt published in England his *Observations on the London Bills of Mortality*; Riccioli made the first serious attempt to estimate the population of the earth, and Graunt, of a large city. About a century elapsed before these beginnings developed into a national census along modern lines. During this interval there

were various attempts to enumerate the population of cities, provinces or cantons, but no successful attempts to count the whole population of large countries.

Perhaps the earliest of these preliminary efforts was a municipal census of the entire population of Nuremberg, taken in 1449. All previous enumerations both in the western world and in the Orient had been limited to certain age classes or other classes of the population or to hearths and households and thus had lacked the inclusiveness characteristic of the modern census. In the middle of the fifteenth century Nuremberg was threatened with a siege and the city fathers ordered a return of the entire population and of the available food supply. The results were guarded as a state secret and were not made public for more than two centuries. Other municipal censuses and censuses of provinces or of Swiss cantons were taken in the fifteenth and sixteenth centuries. All these, however, were merely foreshadowings of the later development.

The honor of introducing the modern census has been claimed for several countries, notably Canada, Sweden and the United States. The periodical enumeration established in the colony of New France in 1665 and continued in Quebec until 1754 has been called "the earliest of modern censuses" (Baines' article on "Census" in *Encyclopaedia Britannica*, 11th ed. 1910). The first of these, however, was later than Virginia's enumerations of 1624-25 and 1634-35, while the population affected was not significantly larger. The Canadian censuses, however, unlike those in Virginia, constituted a regular series and recorded the name of each person and various facts about him gathered by a house to house visitation. They included the villages of Quebec, Three Rivers and Montreal as well as a farming population scattered for some 200 miles up the St. Lawrence valley.

Sweden's claim to priority is based on a census taken in 1749, which according to Guinchard (*Sweden: Historical and Statistical Handbook*, Stockholm 1914) merits recognition as the original census. This was the first of a series which the Swedish government has continued without interruption down to the present. The Swedish census was based at the start on parish registers established in 1686, when each pastor was instructed to maintain not only registers of births and deaths and of all persons moving into or leaving the parish but also a list of its members. In 1748 a supplementary law

was passed requiring three tables to be prepared annually for each parish, one for births, a second for deaths and a third for the whole population. These parish reports went to the Home Department, where a summary for the year 1749 was prepared with the help of Wargentin, secretary of the Swedish Academy of Sciences.

An enumeration in Denmark and Norway in 1769, when they were under one government, was entrusted to private persons and is admittedly somewhat unreliable. The first general census of Spain, taken in the same year, encountered not a little resistance from the people, who feared that it was a preliminary to increased taxation and accordingly tended to supply incomplete or inaccurate information.

As a result of these experiments the few European students and administrators who considered the problem in the last half of the eighteenth century seem for the most part to have formed the opinion that an attempt to enumerate the residents of a large and populous country would be shipwrecked on administrative difficulties. Necker had written that it was impossible to make a general census of so extensive a country as France, and similar views had been expressed by German and English scholars. Even as late as 1827 Quételet (*Recherches sur la population*) desired to estimate the population of the Netherlands, which then included Belgium, by the method that Laplace had proposed a generation before, i.e. by enumerating the population of certain districts, determining for them the ratio between the population and the number of births or of deaths and applying that ratio to the whole country. This he proposed because he was skeptical of the census method.

Undeterred by the failures, or at best the partial successes, in these European countries, and faced by a serious and threatening political problem, the drafters of the American constitution of 1787 inserted therein a provision that an "enumeration shall be made within three years after the first meeting of the Congress of the United States and within every subsequent term of ten years." A similar plan for a periodic census had previously been set forth in the first constitution of New York state. It prescribed "that as soon after the expiration of seven years subsequent to the termination of the present war as may be, a census of the electors and inhabitants of this State be taken. . . . And further that once in every seven years after the taking of the said first census a just account of the electors resident in each county shall be

taken." But the first enumeration in New York state under this provision was not taken until 1795, five years after the first federal census, and reported merely the electors, not the entire population.

The constitutional provision for a decennial census of the United States was not, however, an imitation of the New York constitution or of the practise of any European country. Nor is it to be ascribed, as Moreau de Jonnés ascribed it in 1847 (*Éléments de statistique*), to the fact that the members of the Constitutional Convention appreciated the value of statistics so keenly that they instituted the statistics of their country on the very day that they founded their government. The provision for a decennial census grew out of a protracted controversy between the large and the small states. Under the Articles of Confederation then in force each state had one vote and the congress one chamber. In the Constitutional Convention the small states insisted on retaining their equality; the populous and wealthy states demanded a weight in the councils of the nation proportional to their population and wealth. The compromise which was adopted provided for a legislature of two chambers, in one of which, the Senate, the claim of the small states should be granted, while in the other, the House of Representatives, the claim of the large states was allowed. When this agreement was reached, it was a short step to recognize that a periodic readjustment of the number of representatives in the lower House to changes in the population or the wealth of the states was desirable in a country where growth was rapid and uneven. It was decided to base representation on population, to count the slaves as three fifths of the same number of free persons and to enumerate the population every ten years.

On the surface the American census seemed like a political accident, but there is a real connection between democratic forms of government, with their attendant publicity, and the taking of a census. Until the nineteenth century the statistical data gathered by countries of continental Europe were usually treated as secrets of state. The modern census began in the United States in close association with democratic forms of government, and even at the start the results were immediately made public. Along with the growth of democracy in the nineteenth century there was an attendant spread of census taking. When the United States assumed responsibility for the government of Porto Rico and the Philippines one of its early measures

was the taking of a census, in order to provide information needed in setting up a more democratic government. The effort to take a census in China in 1910 resulted from a plan to establish local representative institutions in that country.

Whether Canada or Sweden or the United States be regarded as the originator of the modern census there can be no doubt that the periodic censuses of the United States have been preeminently responsible for introducing the practise into other countries. The history of statistics has been traced more carefully in Germany than elsewhere, and German students ascribe the origin of modern census taking to the United States. Thus Wappäus said in 1881 (*Einführung in das Studium der Statistik*) that the United States was the first to undertake a census embracing all persons in a country. Von Mayr declared in 1895 and again in 1914 that the United States introduced censuses proper, which give not only the total number of persons but their main social classes (*Statistik und Gesellschaftslehre*). Van der Borght in 1911 called the census of the United States taken in 1790 the first census in the modern sense of the word (*Handwörterbuch der Staatswissenschaften*, 3rd ed., vol. viii, p. 502).

The first English census was taken in 1801 through the agency of the local overseers of the poor, or substantial householders. There is apparently no evidence that the sponsors knew of the American experiment eleven years earlier. This English census reported not merely the population classified by sex, but also the number of families and inhabited houses and the number of persons chiefly employed in agriculture, trade and manufacture or handicraft. At the same time the number of baptisms and burials in each tenth year through the eighteenth century and of the marriages in each year between 1754 and 1800 was reported by the parish rectors, vicars or curates.

France ordered a general enumeration in 1800, the results to be reported to Paris within two months. But the administrative machinery was inadequate and when at the end of two years the figures were received they were not treated seriously. The same was true of the second French census in 1806. It was not until thirty years later that the French government took a careful census by modern methods and with trustworthy results.

Block in 1886 claimed that the census of Paris in 1817 was the first real census, since it introduced schedules giving the names of all

persons whether adults or children, masters or servants, a procedure extended in 1836 to all France (*Traité théorique et pratique de statistique*). Whether the claim be admitted depends mainly on whether the reporting of the name of every person is regarded as the essential characteristic of a census.

Probably no European census has had a more widely extended influence than the Belgian census of 1846. Nearly twenty years earlier Quételet had laid before the Belgian Academy of Sciences a study of the Dutch births, deaths, etc. in the hope of inducing the government to take a census, and in 1841 Belgium had organized a central statistical commission with Quételet as its president. Its main work at the start was in organizing and taking a census of the kingdom. At that time Quételet was perhaps the most widely known and influential of living statisticians and the Belgian census gained influence from his prestige. It was carefully planned, and by the use of a schedule with one line for each person provided space for answers to numerous questions. The most striking and important innovation was a careful analysis and critical interpretation of the returns. As soon as Italy and Germany had succeeded in achieving unification of the many parts into which they had been broken state wide censuses were organized, by Italy in 1861 and by Germany ten years later. The first Russian census was taken in 1897, almost at the end of "the statistical century," and with that step the census was extended over almost all of Europe.

Census taking has been carried also to more remote countries until now perhaps two thirds of the earth's population has been enumerated. The percentage is steadily rising, and practically the only unaffected and densely populated regions remaining are China and some independent or semi-dependent districts of Africa.

The returns of the first American census, as of the eight which followed, were gathered by federal marshals and assistant marshals in the judicial districts. In 1790 the returns gave the total population, white (male and female) and colored (free and slave). The white males were classified into those above sixteen years of age and those below; but Madison's proposal of a simple occupational classification, while approved by the House of Representatives, was rejected by the Senate.

On the eve of the second American census the Connecticut Academy of Arts and Sciences with the support of its elder sister, the American

Philosophical Society, petitioned Congress to direct that the census be taken in a more detailed manner. The memorial of the American Philosophical Society doubtless received special attention inasmuch as its president, Jefferson, was vice president of the United States and ex officio president of the Senate, the body to which the memorial was addressed. Both petitions urged a more detailed classification of the population by age, in the hope of getting light upon the average duration of human life. In the census of 1800 the whites (male and female) were classified into five age groups.

The American censuses before 1850 made the family the unit and reported only a few details such as the number of persons of each sex falling within the different specified age groups. Beginning with 1850 the individual became the unit, and additional details, such as the sex, age, race, birthplace and occupation of each person were reported. This great change in procedure, perhaps the most important in the whole history of the census, was made almost simultaneously on both sides of the Atlantic. It furnished, far more effectively than had earlier methods, guarantees of the accuracy of the enumeration and means of detecting inaccuracies. The material thus obtained also permitted more detailed and complicated tabulations.

The change has often been attributed to the direct influence of Quételet and the Belgian census of 1846. But the immediate prototype of the American census of 1850 was the slightly known Boston census of 1845, the creator of which, Lemuel Shattuck, was called to Washington in 1849 and contributed greatly to organizing the federal census of the following year along similar lines. Shattuck seems to have drawn heavily for his ideas upon the Irish census of 1841, organized by Thomas Larcom. Larcom in turn had found and utilized many suggestions in a report upon the approaching British census of 1841, presented in April, 1840, by a committee of the Statistical Society of London. This committee had corresponded with Quételet, and may have derived many suggestions both from him and from John Rickman, who had prepared the reports on the first four English censuses (1801-31). Whether the lineage goes further back, as Block claimed, through the French census of 1836 to the Paris census of 1817 and Joseph Fourier, has not been determined. What connection there was between the United States census of 1850 and Quételet was probably through these links. The main innovations com-

mon to the Boston census of 1845, the Belgian census of 1846 and the American census of 1850 were: making the individual rather than the family the unit of enumeration; increasing greatly thereby the amount of information gathered; and interpreting the information in a critical text.

After these changes had been made and at least four items of information had been asked about each free inhabitant the number of possible tabulations was greatly increased and the work of the central office in supervising the enumerators in the field and in planning, producing and interpreting the census tables became steadily more important. At the start hand tallying was employed in building up tables from the answers on the schedules—a method which required expert clerks and careful supervision, since a misplaced tally is almost sure to go undetected. Labor saving in tabulation began in the United States as early as 1872, when a device was introduced for exposing only those columns on the large tally sheet which were for the moment in use. This primitive machine was of much help in tabulating the results of the American census of 1880. In an effort to reduce the mechanical labor of hand tabulation two other methods have been tried. One consists of a schedule card for each person, filled by the enumerator in the field and used in the office as a classifying and counting unit. This method has been employed in Italy, Prussia and Massachusetts. The other is the use in the office of slips or cards or chips, one for each person, to which all the information needed for tabulation is transferred. This originated in Bavaria in 1871 and was used later in Massachusetts and India. "In order to reduce the labour of filling in the slips various devices were resorted to; slips of different colours were used for the different religions; sex and civil condition were indicated by the shape of, or symbols printed on, the slips" (Risley, H. H., and Gait, E. A., *Census of India*, 1901, 4 vols., Calcutta 1903, vol. i, pt. i, p. xv).

Since 1890 these devices have been slowly displaced by mechanical methods of tabulation, usually employing an electric current. In American field work enumerators use a large schedule printed on both sides and providing room for answers concerning one hundred persons, the answers for each occupying one line across the schedule. The statistical information thus obtained about each person is transferred in the central office to a small tabulation card by

punching small holes, the location of each indicating the nature of the answer. By the aid of an electric current guided to the proper dial by the location of these holes, it is possible to tally simultaneously instead of successively, and with mechanical accuracy. This device, originally invented by Hollerith and first used in the American census of 1890, greatly increased the scope of the tables and made the tabulation of complicated facts (e.g. number of married male barbers 25-34 years of age) almost as easy and cheap as the tabulation of simple facts (e.g. number of males). These complicated tabulations are of primary importance in turning census material to scientific use. As a result of this innovation the tables in the census of 1890 increased in number and complexity over those in the preceding census almost as much as had those in the census of 1850 over the 1840 tables.

With the development of the census the inquiries on the population schedule have tended to multiply. Thus in 1850 four questions, and in 1930 seven, were asked about every resident of the United States; in 1850 six questions, and in 1930 ten, were asked about everyone in a defined class, e.g. about the literacy of every person over a specified age. This change has greatly increased the amount of possible tabulation; by adding to the enumerator's load it has further increased the danger that he may neglect questions less readily answered. There is a great difference in difficulty, for instance, between reporting the sex of an individual and reporting the industry or business in which he works. The tabulation of occupations is almost as difficult as that of all the other answers combined. Some countries in order to secure a detailed and accurate picture of the industrial grouping of the population have taken special censuses of occupations and industries at a different date from the regular population census. Since industrial legislation in the United States falls within the field of the states an industrial census is of immediate importance for the latter and is not likely to be introduced unless it is called for by the states to furnish a basis for their legislation.

Following the example of the United States, a number of states have taken periodic censuses and even incorporated provisions for them in their constitutions. In a few cases, notably those of Michigan in 1854 and later, New York 1855, 1865 and 1875, and Massachusetts and Rhode Island 1875 and later, the results have been of scientific value. For the most part, however, these state censuses were taken by persons not

trained for such tasks and the results were insignificant or serviceable only for reapportioning members of one or both branches of the state legislature. The tendency of the states in recent years has been to abandon this practice and to rely upon the federal censuses both for the figures needed in state apportionment and for information about state conditions in various fields.

Very few American cities have taken censuses of value. Usually they are entrusted to the police department and thus become purely political or administrative in character. The only important exception to this rule is the Boston census of 1845, already described. In European cities statistical offices with trained staffs are more generally found. Although these often take over the local work of national censuses and add to the general schedule approved questions of local importance, such as those about buildings and housing, population per room, &c., there are few cities which have developed independent censuses.

After it had been found that the enumeration method was serviceable for counting persons and that its results were so much more accurate than any method of estimate that they justified the added labor and money required, the question arose whether the same method of complete enumeration might be found serviceable in other directions. In 1850 a census of agriculture was taken in the United States. The enumeration unit was not the resident but the farm, about which many questions were asked involving area, total and improved, produce of various crops, number of various kinds of livestock, etc. This method of obtaining agricultural information has spread to other countries but not so fast and far as the censuses of population. In the United States the agricultural census is now taken every five years but the intercalated ones are restricted in scope and less expensive. These returns from an agricultural census are treated as bases of reference for crop estimates of post-census years. Censuses of agriculture involving a call at each farm by an enumerator were introduced much later than censuses of population and are found today in only a small proportion even of the leading agricultural countries. In Great Britain agricultural censuses were taken in 1906 and 1925 but the farm schedules were sent out by mail. The agricultural returns which have been obtained in Germany at intervals of five or ten years are as a rule not true censuses but estimates made by the officers of each commune.

A census of the products of industry was introduced in the United States as part of the census of 1850. The unit at first was the producer or producing establishment, including "all kinds of mercantile, commercial or trading business . . . confined to dealing and exchange of articles of merchandise or manufacture." Thirty years later the phrase productive industry was defined as including "not only all factories and large works but also the mechanical trades, as blacksmithing, coopering, carpentry, etc." Since 1905 the census of manufactures, which then began to be taken every five years and now is taken every two, has omitted these hand industries or neighborhood industries, which never were completely enumerated, and has been restricted to industries conducted under the factory system.

The testing of the accuracy of a census is difficult because there is no standard more trustworthy by which its results can be measured. But a census is sometimes discredited by the inconsistencies between its different results or by divergences between its figures and those of earlier or later enumerations. The results of the census of 1870, accepted without question at the time, are now admitted to have been defective especially in the southern states, although the proportion of omissions is often exaggerated. The accuracy of a census is ordinarily judged by the accuracy with which the population has been counted, and that total under American conditions is, according to the expert opinion of Francis Walker and Carroll Wright, probably within one percent of the truth. But a complete census is composed of answers to many inquiries, each with its own degree of error. Negroes are enumerated less accurately than whites and the probable error of that count may run as high as two percent. Age is very badly reported, especially among adults; who as they grow older tend to become increasingly inaccurate in this respect. Errors from this source decrease, however, from census to census. The foreign born are, with the exception of the Negroes, least accurate in reporting their ages. The actual number of divorced persons in the country at a given date is not far from twice the reported number. Whenever the conditions permit and the degree of error is important, the probable error of each class of answers should, in spite of the difficulty of the task, be estimated.

Such an estimate is a part of the interpretation of the results. Some American officials have thought it best to publish tables with little com-

ment, and thus leave the public to make their own interpretations. This cautious position, while at the start it was probably wise and in some controversial fields may still be justified, has been generally abandoned for census statistics. It remains true, however, that a writer in a governmental publication is less free than a private citizen, and it becomes a question how far an official commentary should go. The interpretations should probably be limited to those "inferences which would be accepted as almost certain by anyone competent to weigh the evidence and which seem to be of general rather than of merely local interest or importance" (United States, Census Office, *12th Census 1900, Supplementary Analysis and Derivative Tables*, Washington 1906, p. v).

Because of the temporary character of American census organization before 1902 and the pressure upon the office staff both before and after that date, the interpretation in many cases was for a long period inadequate or perfunctory. This shortcoming has recently been overcome in part through a series of census monographs prepared usually by collaboration between the bureau and outside scholars.

CENTANI, FRANCISCO (dates of birth and death unknown), seventeenth century Spanish economist. His only work which is extant is a memorial, *Tierras; medios universales . . . para que . . . tenga la real hacienda dotación fija para asistir a la causa pública* (Madrid 1671). He is considered a precursor of the physiocrats because of his doctrine that land is the "true" and "physical" source of wealth and should bear the brunt of taxation. His projected reforms, prompted by notorious frauds in the fiscal system and excessive administrative expenses, centered on the abolition of vexatious indirect taxes which hindered economic progress. Malversation in the *real hacienda* and poverty among the people would cease with the substitution of a single tax upon land, with no exemptions for the nobility or the church. The tax would be levied

on the basis of a statistical survey of fertility and the value of crops. This concept of an *impôt unique* contrasts with such of his other ideas as have a mercantilistic stamp. After describing the natural resources of the realm Centani argued that his proposals, which included restriction of the importation of manufactures, would increase the population of Spain from six to thirty million. Associated with his consideration of land as the only real wealth is his belief that "the greatest wealth consists in increasing families." Following the thought of contemporaries Centani decried monetary inflation, pointing out that although there was twice as much money in Spain in 1670 as in 1630 the majority of the people were living in greater distress.

CENTER PARTY, GERMANY. *See* PARTIES, POLITICAL; CATHOLIC PARTIES.

CENTRAL AMERICAN FEDERATION. Perhaps the earliest step in the direction of Central American federation was the organization of the captaincy general of Guatemala by the Spanish government in 1527. A similar centripetal tendency operated during the brief period when, on their severance from Spain, some of the Central American provinces were joined to the Mexican Empire. After the dissolution of the latter in 1823 the provinces of Costa Rica, Guatemala, Honduras, Nicaragua and Salvador established the first Central American Union, for which a constitution, evidently patterned after that of the United States, was promulgated on November 22, 1824. This federation was dissolved in 1839 under the impact of intense party strife, in which the radicals or liberals, who favored federation, were driven from power by the aristocratic and clerical elements, largely because of their strong anticlericalism. The idea of a central organization did not die out in Central America after the dissolution of the first union. In some of the constitutions subsequently adopted by independent nations of Central America the hope was expressed that at some future time the old federation would be reestablished. This sentiment was embodied in the Costa Rican constitution of 1847, the Salvadorean constitution of 1886, the Guatemalan constitution of 1887, the Honduran constitution of 1904, the Nicaraguan

constitution of 1905 and the Costa Rican constitution of 1917.

After the collapse of the original union the adherents and opponents of federation in each state maintained interstate affiliations. Mid-century Isthmian politics involving Great Britain and the United States and, somewhat later, the filibustering expeditions of William Walker increased union sentiment, but several attempts in the forties by Honduras, Nicaragua and Salvador—the three states most alike with respect to racial elements and social conditions—to set up loose federations failed. With the decline of the early parties favoring and opposing federation the important factors in the situation became individual statesmen and dictators. In 1885 General Justo Rufino Barrios (*q.v.*), president of Guatemala, having failed to bring about a union by peaceful means, proclaimed the establishment of a Central American Union, placed himself at the head of an army and summoned the other republics to join the movement. He met his death in the first battle with the soldiers of Salvador. Eleven years later the presidents of Honduras, Nicaragua and Salvador agreed to form the Greater Republic of Central America. Although this union was recognized by the United States, it was short lived. Opponents of the Greater Republic declared that it was the work of a few men, not the wish of the people.

Factional disputes of this sort over leadership, in countries unstable in their democratic organization and frequently embroiled with conflicting dictatorships, have thus stood in the way of Central American federation. Other centrifugal forces have been the opposition of politicians in different sections to centralization because of the strength of local interests and the fear that political preferment might be lost. The difficulties of intercommunication between different sections of Central America have encouraged particularism and checked any move toward the unification of the different sections. Economic forces have not always worked for harmony: the banana planter of Nicaragua has little in common with the coffee planter of Salvador.

The United States has generally favored a federation of the republics of Central America. Such a policy, recommended by a desire to further political stability on the American continent, has been fortified by the necessity for safeguarding American economic interests and giving no ground for European intervention. In 1874 and again in 1880 the United States

evinced an interest in federation, and such an interest was also part of Blaine's pan-American policy as secretary of state. Roosevelt's corollary of the Monroe Doctrine—that it is the duty of the United States to preserve peace in Central America—led him, with the aid of President Díaz of Mexico, to promote the Central American Conference at Washington in 1907. This conference resulted in the framing of a series of treaties which aimed to remove Central American discord and encourage the formation of a firm union: recognition of unconstitutional governments was discountenanced; intervention and the fomenting of revolt in neighboring states were banned; Honduras was neutralized; a Central American Court of Justice and a Central American Bureau were created. In 1922, when some of these treaties had lost their force, the United States sponsored another conference at Washington, where treaties were again framed, dealing with the establishment of amity, the reduction of armaments and the creation of an International Central American Tribunal.

At the Central American Conference of 1907 the delegates from Honduras and Nicaragua had urged that an intimate union among the Central American republics was needed, while other delegates declared that as yet this was only a noble aspiration. This view is borne out by the results of a move toward a Central American Union that took place in 1921. On January 19 of that year a treaty was signed at San José by representatives of Guatemala, Salvador, Honduras and Costa Rica. This "pact of union" sketched a provisional constitution for the four republics that wished to reconstruct the Federal Republic of Central America. This constitution declared that united into a "perpetual and indissoluble union" those republics would henceforth constitute a sovereign and independent nation designated the Federation of Central America. So far as the federal constitution would allow, each state in the union was to preserve its control of local affairs and was to exercise all the powers not delegated to the federal government. Until the central government could negotiate new treaties the respective states were to fulfil their existing treaties with foreign nations. The state constitutions were to remain in force so far as they were in harmony with the federal constitution. But Nicaragua opposed this treaty because it impinged upon her transisthmian canal interests, which were protected by the Bryan-Chamorro Treaty with the United States. Nevertheless, arrangements were made

that the new confederate flag should be unfurled on September 15, 1921. Eventually, however, Costa Rica, which has generally been cool to federation, chiefly because of its geographical isolation and the large European elements in its population, turned against the confederation, and a coup d'état that took place in Guatemala city in December, 1921, completed the downfall of the projected Federation of Central America.

CENTRAL BANKING. The term central banking is of comparatively recent origin, not being widely used before the beginning of the twentieth century. While some variations in the meaning of the term survive even to the present, the consensus of opinion now limits the designation "central" only to those banks which have a distinctly public purpose, that is, banks which transact business not primarily for the purpose of making profit but rather for the sake of the ulterior effects upon the money market and upon the banking structure in general. Among such banks we may distinguish bankers' banks, which have virtually no dealings with any customers except bankers and governments, and banks which do business with all classes of customers, although they are disposed to limit their larger dealings to operations in which other banks are involved or in which the government largely figures.

Prior to the World War most of the larger European countries had well developed central banks, although these varied a good deal among themselves in detailed function. In the United

States, however, genuine central banking was unknown, the First and Second Banks of the United States having been enterprises of a quite different nature; likewise in South America, notwithstanding the existence of several so-called central banks, there was no well established system; and little progress in this direction had been made in the Orient. During the World War experience showed that central banks can exert a considerable degree of control over the price level and are in a position to render substantial assistance to governments in rectifying their financial affairs. As a result a movement set in for the establishment of central banks; it was strongly furthered by the resolutions of the Genoa Conference (1922) which advised the organization of a central bank in each of the new countries created by the Treaty of Versailles. Several such banks were promptly established, and in practically all of the central banks a new conception of function was developed during the decade following the war. This movement was marked by some exaggerations; over-sanguine opinions as to the possible power and effectiveness of central banks were frequently expressed. During the latter part of the decade, however, opinion swung in the opposite direction; people were disposed to minimize the scope of action of central banks and to restrict them to a position similar to that which they had held prior to the war.

The primary function of central banks is to maintain the banking reserve of the country at a sufficiently high point and in a sufficiently liquid condition. By this is meant (1) the maintenance of what is considered an "adequate" cash reserve against the bank credit of the country, such reserve to be held in the vaults of the central bank or in those of other banks or divided between them; (2) the defense of the entire specie stock of the country against undue depletion by exportation or unwarranted increase through importation; (3) the maintenance of an adequate note issue convertible into bank credit through deposits at any time and presumably convertible into coin upon demand.

Experience has shown that in order to perform its function the central bank must have the power to supply or "create" in the course of its operations ultimate reserve funds in some fashion. This is accomplished by investing the central bank with a monopoly of banknote issue or, at least, with a power of note issue superior to that of other banks, these notes being used by the latter as vault reserves. The same effect

may be achieved by requiring the other banks to maintain "reserve balances" with the central bank—balances which are the result of either cash deposits or paper rediscounts. In order that the central bank may at all times be ready to meet the requirements of other banks for more reserves it is usually authorized to rediscount the paper brought to it by other banks (normally with their endorsement), the proceeds then being represented either by issues of its own notes or by credits on its books considered as reserve for such other banks. The fundamental problems, therefore, confronting the central bank are the note issue policy—or the total amount of notes and the basis on which they should be issued—and the discount policy. The latter is usually thought of as including the determination of the kind of paper which the bank will ordinarily admit to rediscount, the rate at which it will admit such paper and the extent to which it is willing to go in granting rediscounts both in the aggregate and to any individual banking institution.

During the first half of the nineteenth century there developed in Great Britain a controversy with respect to the basis of note issue, which had an important bearing upon the fundamental problem of central banking. The currency school put forward the view that note issues in order to be "safe" should be protected by a reserve of specie so that all additions to the notes in circulation beyond a specified amount (protected by collateral, preferably in government obligations) be covered unit for unit by specie. The banking school, on the other hand, held to the view that the proper basis for note issue was the development of business or exchange, as evidenced by the amount of liquid commercial paper discounted with the issuing bank. This was later called the "commercial asset theory" of currency issue. The British Bank Act of 1844, imitated in the National Banking Act (1863) of the United States, represented the triumph of the currency school. Most of the continental note issue systems, however, rested upon the banking theory, and the Federal Reserve Act, passed in 1913, adopted virtually the same position. When in the course of time banknotes declined in importance as an integral part of the country's currency, the older controversy developed into a discussion as to the type of paper which the central bank should discount in order to provide the basis for its deposit credits. There are those who insist that it should discount the obligations

of other banks with sound collateral attached, and on the other hand those who would limit the discount operations of the central bank to liquid paper growing out of bona fide commercial transactions.

In recent years there has become apparent also a pronounced difference of opinion as to the scope of central bank activity. According to the exponents of the so-called emergency point of view the central bank stands ready to act "like a fire engine," putting out financial conflagrations as they develop—an emergency institution, really active only from time to time. The adherents of the banking point of view maintain, on the contrary, that the central bank should function like a bank and not like a relief institution; its work should be constant and regular and its policy should be that of shaping and adapting itself to critical conditions as these arise. Although the extent of its participation would necessarily vary, it should be a constant factor in the money market. The difference between these points of view is reflected most clearly in the scope which they allow to the so-called "open market" operations of central banks, that is, those operations in which the central bank goes out into the open market and seeks business, buys and sells paper and otherwise takes the initiative in injecting or withdrawing credit. When the Federal Reserve Act was under advisement strenuous efforts were made by the banking community to prevent the incorporation of open market powers in it, but since the close of the war the continuous and large use of these powers has been recognized, both in America and Europe, as practically indispensable in the operation of central banks. The relation between discounting and open market operations necessarily varies with varying market situations. Since the central bank is not properly concerned with the satisfying of ordinary credit needs, its activity is generally at its lowest when the operations of other banks are at the average or usual level and the volume of their credit extension shows no appreciable change. It is this fact which probably gave rise originally to the emergency relief theory. Yet conditions seldom are normal or average. The great transactions of governments, which are now largely in the hands of central banks, disturb the market; international banking operations affect and readjust market conditions; speculative processes may have a similar distorting effect. Thus, although the degree of its participation varies, the central bank in prac-

tise is called upon to be steadily in the market.

Whether the central bank remains an emergency relief institution or functions as a constant factor in the money market, it is desirable that its head office be located in the principal financial center of the country. But such functions as clearing on its books a considerable proportion of the country's check transactions, regarded within recent years as pertaining to central banks, and acting as a fiscal agent for the government have obviously led to a need for branches. Most central banks have developed accordingly larger or smaller groups of such branches. The Bank of England, for example, has 10; the Bank of France, about 660. The Federal Reserve system in the United States provides for 12 central banks, each operating in its own district as a separate corporation independent of all others; but all of them are supervised by a central board, possessing such extensive powers of control over their policy, expenditures and personnel that it may be treated, in theory at least, as a central board of directors of which the local institutions are in a sense branches. The Federal Reserve Banks have established branches of their own which numbered 25 in 1930, but the whole theory of their operation and of the degree of their independence still remains unsettled. The problem of the proper relation between the head office and the branches of a central bank is much more than a mere matter of technique; the delimitation of the degree of independence of the branches is conditioned by the view taken as to how far it is possible and expedient to go in setting up local discount markets.

Some authorities declare that in addition to maintaining the banking reserve of a country in a satisfactory condition central banks should attempt to regulate the supply of credit in such a way as to bring about readjustment in cases where relationships between purchasing power and the price of goods depart from an average or normal level. This phase of central bank activity, the possibility of exerting "credit control" in order to stabilize the price level, came into great prominence after the close of the World War and has continued ever since to excite largest interest. Obviously, such use of central banking is possible only if the central bank has the power of directing and regulating the volume and use of bank credit in general and if bank credit is, at least, the most important price determining factor.

In order that the first of these conditions be

realized in practise it is necessary that the central bank exercise a considerable degree of control over other banks in the country. It is supposed that the central bank, by changing its discount rate or by "rationing" its credit to various classes of customers, can regulate the amount of credit available, within a certain range of cost, to other banks. Being thus able to add to, or to subtract from, the reserves of other banks the central bank is in a position to force them to broaden or diminish their lending, to determine the expansion or contraction of their credit to the public. It is argued further that if other banks do not offer to deal with it in a volume sufficient to enable it to obtain such results the central bank may undercut them by going into the open market, thereby compelling them to regulate their rates more or less with reference to its own rate and in some measure at least to adjust their conditions of lending to those made by the central bank.

The ability of a central bank to exercise such a degree of control depends upon its power to make its discount rate fully "effective." There are conditions under which this seems to be impossible. For example, if the price level is already advancing at considerable speed it is probable that the raising of the discount rate may be relatively ineffectual, as was demonstrated by the experience of the European central banks during the post-war period. Similarly, when other banks are not as yet at the point of being "loaned up" and are themselves of substantial size, with resources comparable to those of the central bank (as in England), they may be quite able, either singly or by joint action, to neutralize except within a restricted range of transactions the efforts of the central bank in the open market.

In this connection it is interesting to observe the differences in the mechanisms employed by central banks in the regulation of credit extension by other banks. The older practise of the Bank of England and of other central banks has been founded upon the view that the discount rate of the central bank should be the controlling factor and should "lead" the market. The Bank of England has thus habitually sought to have its official rate slightly higher than the market rate, with the purpose of penalizing those banks which sought to enlarge their credit by borrowing from it; at the same time through its private rate, at which it discounted the paper and advanced loans to its non-banking customers, it sought to drive the other banks into

conformity with its policy by compelling them to charge rates similar to those which it was itself enforcing. In the United States the banking authorities have never accepted the original Bank of England practise but have usually fixed a rate lower than that of the open market. The Federal Reserve Banks, reluctant to raise discount rates for the purpose of curtailing the supply of credit in the market, have made their increases usually after, instead of before, open market changes. They have, therefore, in a good many cases been disposed to substitute a rationing of bank credit for changes in the discount rate and have sometimes sought to curtail credit by refusing to discount specified kinds of paper. This has never been very successful and the prevailing opinion undoubtedly regards the established practise of the Bank of England as the correct one. The older technique has, however, been greatly disturbed by the development of new conditions since the close of the war.

If central banks are to be in a position to regulate the price level it is also necessary that bank credit play a decisive role in the determination of prices. The advocates of price stabilization through credit control maintain that the price level is governed, by and large, by the volume and velocity of currency, an overwhelming proportion of which is made up of bank credit instruments such as checks and banknotes. Without going into a detailed analysis of this theory it may be observed that even if its soundness be admitted for normal conditions factors operating entirely on the goods side of the equation of exchange, such as invention of new labor saving devices or of new methods of distribution, may effectually change the direction of prices. It is also doubted by some authorities whether actual conditions of competition and mobility are such that a change in the volume or velocity of credit is felt immediately throughout the entire field or indeed fully felt at any time. Moreover, the existence of artificial price control in certain important branches of economic organization may result in greatly altering the effect of changes in credit supply upon other groups of prices. A practical argument advanced against this theory is that statistical information is too fragmentary and inadequate to permit the day-to-day regulation of bank policy with a view to keeping the price level stable. Thus the United States Federal Reserve Board has officially asserted that in fixing discount rates it will often be true that statistical analysis is too late or too inadequate

to be of service and that in lieu of conclusions based thereon the use of "judgment" or conjecture is a safer guide. Most persons, however, admit that where practical stability in the price level or regulation of the increase or decrease at a moderate rate is a prime prerequisite central banking policy should so far as possible be directed to the purpose of bringing that about. There is still difference of opinion as to whether price stability should take precedence over all other purposes.

In the course of its routine business a central bank establishes contacts not only with the government and the other banks in the country but also with banks in foreign countries. Under the conditions of international economic and financial interdependence which are characteristic of the present economic order in the western world regular relations with foreign banks are to be regarded as virtually mandatory. The exigencies of credit control and of such financial ties between governments as are likely to arise in war time enhance the scope and importance of these international relations and may lead to the development of cooperative relationships between central banks. Of recent years a good deal has been said about the necessity and practicability of such international cooperation. Before the war in times of a world wide crisis or of special domestic pressure central banks successfully undertook international transfers of gold and on one or two notable occasions interbank rediscounting. The satisfactory results achieved in these isolated instances encouraged economists to suggest the possibility of a world bank, an idea which was discussed as eagerly as that of international money. After 1914 war necessity led to an informal pooling of resources by central banks among both the Central Powers and the Allies. When the United States entered the war, the funds of the Federal Reserve system were also thrown into the common stock. Cooperation at that time did not extend to the imposition of uniform currency and credit regulations, and independence of the price levels was maintained through the artifice of exchange "pegging." War experience, however, had been so striking that it stimulated a desire for joint action in the period of reconstruction. The work of the Gold Settlement Fund of the Federal Reserve Board had attracted wide attention, and discussions at Versailles had later led to proposals for an international gold settlement plan. These proposals came to nothing

because of the mutual distrust which prevailed.

With the complete collapse of currency and domestic values in Germany it became evident, however, that the restoration of normal conditions in the field of currency, foreign exchange and international trade depended to a considerable extent upon the assistance which central banks in a strong position and with large holdings could extend to weaker institutions in other countries. It was believed that the anticipated renewal of the pre-war "scramble for gold" could be prevented only by the cooperation of the central banks of the world. After 1925 a series of agreements was therefore entered into by various leading central banks, under which they promised to provide means for safeguarding the normal functioning of the new currency systems established in the several countries following a period of stabilization. The Federal Reserve Bank of New York, for example, undertook to support the Bank of England in putting the British currency stabilization legislation upon a permanent basis by obligating itself to purchase bills up to a specified amount at a rate of discount fixed with reference to its own prevailing rate, if such assistance was needed. As such agreements became more numerous and complex, the ordinary business problems to which they gave rise increased in number and urgency; central banking conferences were therefore called from time to time. The subjects discussed at these meetings and the results of the discussions were never made public officially; they were understood, however, to relate to such questions as discount rates, international gold movements, and problems of credit control in which the collaboration of two or more of the banks was considered desirable. These conferences led to a renewal of the discussion regarding the feasibility of a world bank working toward the international stability of price levels and exercising an international control over the several money markets. The conferences had no official status, however, and their outcome was largely dependent upon the personalities of the participants. Nor were they always successful in bringing about genuine cooperation, the outstanding failure being the inability of the Federal Reserve Bank of New York and of the Bank of England to obtain an altogether satisfactory working relationship with the Bank of France during the stabilization of the French currency (1927-28).

Since in several European countries German reparation payments appeared as a significant

element in financial and fiscal budgetary programs, the international financial discussion after 1925 tended increasingly to center about the problem of reparations or issues connected with it. The Dawes plan which was adopted in 1924 provided for the residence of an organized supervisory body in Berlin, but it was understood that Germany would be relieved of this foreign financial occupation as soon as possible. In 1928 the question was raised of a new reparations conference to readjust the entire basis of the payments and to eliminate the foreign supervision which had proven so galling to the Germans. This led to the conference of reparations experts at Paris which produced the Young plan, perfected in detail at The Hague during August and September, 1929.

At an early stage of the preparation of the Young plan the proposal was made to substitute an incorporated "world bank" for the international group in Berlin which until then had administered reparations. There was still much work to be done in steadily receiving and disbursing payments made by Germany and in maintaining German exchange at a fixed parity with other currencies. It was essential that the large transfers involved should never be permitted to interfere with the soundness of the finances of the participants in the reparations plan. It was also recognized that the recipients of the annuities under the new plan might wish to "commercialize" them by issuing securities representing the capitalized value of these annuities. All these operations were found to require sympathetic and experienced handling from day to day and close cooperation between the central banks of the participating countries. A world bank, the feasibility of which was discussed several years before, appeared at this juncture to satisfy an immediate and genuine need. As a result the proposal of a Bank for International Settlements was incorporated in the recommendations of the reparation experts, and in 1930 the institution was organized under a Swiss charter by representatives of the central banks of Belgium, England, France, Germany, Italy and Japan and of an American banking group.

The primary duty of the Bank is to be the managing of reparation payments, but it was also given restricted functions of a general banking nature. It is not permitted to exercise the power of note issue, and in the performance of other functions of a bank of deposit it will encounter difficulties because of its location at

Basle, at a great distance from its chief customers. Nevertheless it is the most distinct development of the world bank idea, the most positive extension of central banking into the international field that has been attempted so far. Such questions as the influence which it may exercise upon credit control in the several countries, the inflationary possibilities which it supposedly offers, the elimination of free fixing of foreign exchange rates which it makes theoretically feasible remain for the present in the field of controversy. These are matters which depend largely upon the policy to be adopted by the management of the new institution.

In addition to its other functions the central bank acts usually as the agent of the government in the money market. It stands ready to make as large advances to the government as banking soundness permits and undertakes to distribute government obligations to other banks and private investors. This practise is justified at present by the magnitude of the financial transactions of the government, which make it an important factor in the money market. Yet the practise is essentially an outgrowth of the peculiar conditions in the early history of central banking. Originally the central bank rendered its chief service to the government by furnishing it with short term accommodation, which too often developed into long term loans. In some cases, indeed, a "permanent" loan to the government was the price paid for the charter and the exclusive privilege of note issue. During the nineteenth century it was recognized, however, that in lending to the government the central bank should act merely as an intermediary, issuing government obligations and selling them to bona fide investors but refraining from any considerable purchasing or lending upon such obligations. The fact that it appeared as the lender to the government caused the central bank to be designated as the holder of government funds, and out of this grew the function of acting also as the receiving and disbursing agent. For a long time the United States under the independent treasury system held out against the establishment of such relationships with banks. During the Civil War, however, it was obliged to reestablish its banking connections, and after the close of the war the increasing complexity of its relations with the business world compelled the continuation of the depository functions of the national banks despite the fact that the subtreasury system was not abolished. In the Federal Reserve Act,

provision was made for transferring the fiscal functions of the subtreasuries to the Federal Reserve Banks, the actual transfer being made in 1920. Since then the Federal Reserve Banks have exercised the same functions as other central banks, issuing and distributing treasury obligations, holding and disbursing government funds and generally performing all duties in connection with custody and trusteeship, except those which for reasons of historical sentiment have been continued in the hands of the Department of the Treasury at Washington. In foreign countries the practise of having the financial business of the government, particularly that involving contacts with the money market, managed with the close cooperation of the central bank is nearly universal. During the World War most central banks became heavily overburdened with government obligations, which accumulated in their hands because it was easier to obtain the funds directly from the central bank than to await the results of a general subscription, or because after great quantities of obligations had been sold it was necessary for the central bank to support the market by lending. The result in either case was the same, the immobilization of the portfolios of all central banks with government obligations. While the Cunliffe Committee Report pointed to the retiring of government obligations from the portfolio of the Bank of England as an essential factor in banking reform, the effort in this direction has been only partially successful. In most countries it has been thought necessary that the central bank should continue its support of the money market and of the public treasury; central banks have therefore continued to be large dealers in short dated public obligations, which by reason of their constant renewal represent really long time indebtedness. The situation has been rendered more complex by the belief that the central bank can effect the stabilization of prices and that dealing in government securities offers substantial aid in this process. Perhaps of even greater importance has been the belief that through the influence of the central bank upon the money market the actual cost of funds to the treasury can be greatly reduced.

The close cooperation between the central bank and the government is at least partly explained by the fact that the government, whether as owner or as the highest authority in the land, exercises in most countries a considerable degree of control over the management

of the bank. In some countries it appoints a group of directors or some of the more important officers of the bank, while in others custom and unofficial pressure make it possible for the government to exert a decisive influence in connection with the management. Thus the Federal Reserve Act requires the direct government appointment of three out of nine directors of each Federal Reserve Bank, while it leaves to a central board, all of whose members are government appointees, the power to veto the rates, salaries and appointments of the several banks. Practically all countries exact from the central bank either a share of profits or a franchise tax, which is often defended on the ground that the privilege of note issue is a profitable monopoly.

CENTRAL LABOR UNIONS. *See* TRADE UNIONS.

CENTRALIZATION. The problem of political centralization is historically rooted in the rise of the modern state. The modern national state sprang from the confusion and conflict of authority which, in the political sphere, characterized the Middle Ages. Allegiance in the later mediaeval period was dispersed among a number of claimants—emperor, pope, king, feudal baron, bishop and free city—each embodying and representing a distinct political idea; their rivalries and strife for power constitute the substance of mediaeval politics. The king was the visible exponent of the concept of a national, territorial state, and his eventual success definitely established the doctrine of

sovereignty as the principal concern of modern political thought. Even in Germany and Italy, where national unity was not attained until the nineteenth century, the state, though frequently of limited extent, came to be recognized as supreme within its territorial limits.

That political authority was centralized in the monarch was indeed the theory, but in actual fact the process of political and legal centralization was nowhere completely and absolutely accomplished. The general recognition of royal supremacy did not prevent the continuance of many vestiges of feudal and local autonomy. In England local government remained until 1835 in the confused and unregulated condition in which it was left by the Tudors with practically no central control. Although justices of the peace were appointed by the crown they were inevitably drawn from the landed gentry of the county and preserved their local character. Sitting in county court they constituted the chief instrument of local government. The parishes preserved their anaemic existence and through their vestries attempted some control of local affairs. In the boroughs many types of government existed, depending upon the provisions of their charters. As a rule they were governed by close corporations. In France the absolute monarchy more nearly achieved a centralized government than elsewhere, but even here the task was not completely accomplished. A unified system of law did not develop, the local *coutumes* resisting the centralizing influence until the revolution. Administration was largely vested in intendants appointed by, and responsible to, the king, but the provincial *parlements* continued until the revolution to constitute centers of local sentiment and barriers to the free flow of national authority. In the American colonies an even greater degree of decentralization obtained than in England, although in certain ones there was a larger democratic element in local government. "The state," says White, "yielded to the county, the county gave way to the town, and the town bowed to its districts." The lack of efficient means of transportation and communication made any centralized system of government impossible. Most of the rudimentary functions of administration were performed by agencies of local government. Generally speaking, the theory of a strong, centralized, national state was modified in practice by a large degree of local autonomy. Particularly did the stiff-necked townsmen constitute a problem for royal authority which could be solved only by com-

promise. The grant of charters to the cities may have theoretically expressed the principle of royal supremacy, but these embodied very substantial rights of local self-government.

While the problem in the contemporary constitutional state of the degree to which government should be centralized has, as indicated above, a historical connection with the process by which the modern national state came into existence, there is no essential identity between the circumstances which favored the growth of a strong centralized government in the fourteenth and fifteenth centuries in England and France and the present tendency toward the concentration of power in a central government. The present problem of centralized versus decentralized government assumes the existence of the sovereign state. The old mediaeval and feudal elements have quite disappeared. Monarchy has given way to constitutional government, but the supremacy of the state is generally accepted. It is no longer a question of whether the state must share its control over the individual with other institutions. The question today is substantially one as to the most expedient and satisfactory organization of power, and this must be answered in the light of a changing economic and social situation and with reference to a gradually clarifying conception of the end and purpose of government.

In one aspect, that of federal government, the problem is closely related to the historical process of national growth and integration. The explanation of such federal states as the United States, Germany and Switzerland is to be found in the historical circumstances that induced "union without unity." The structure of such federal systems represents a balance between the particularism of the small state, jealous of its sovereignty and independence, and the forces of national unification which the modern world has brought into play. Whether these federal systems do not constitute a condition of unstable equilibrium has been a subject of considerable speculation by students of political science. Dicey and Leacock, for example, have maintained that federalism is everywhere to be viewed as a temporary stage in the inevitable evolution toward a strongly centralized form of government. An examination of the constitutions of federal states during the past century and a half reveals a definite centripetal tendency. Not only are those of later origin more centralized than their predecessors, but by the process of constitutional amendment all have become in-

creasingly centralized. On the other hand, the federal system would appear to be the only possible one under which democracy can succeed where widely divergent communities are brought under one government. Even in a country like the United States, where a strong national consciousness and a universal loyalty to the ideals and common interest of the nation exist, the diversity of physical and geographical circumstances makes it probable that this form of government will continue indefinitely.

Even in federal systems the political ideology upon which the national state rests is unquestioned. The state is conceived of as sovereign, although the question of where the attribute of sovereignty is located may be disputed. The theoretical basis of federal government may involve a controversy over "states rights," which assumes at times a highly doctrinaire character. In the United States before the Civil War this became a vital issue in constitutional law and national politics, and occasional echoes of this debate may still be heard. But today we are not much interested in whether sovereignty resides in the Union or in the member states; whether the constitution is a compact between the states or springs from the will and consent of the people of the entire nation. We no longer believe that the division of powers between state and federal government is sacrosanct. And if the courts pay occasional lip service to the "principles" upon which the federal system was founded they have not hesitated to entertain "interpretations" which have fundamentally shifted the center of gravity in the direction of national control. In federal as in unitary states the problem is essentially a pragmatic one as to the most satisfactory organization of political authority.

A general tendency toward centralization has been clearly evident during the last century and is particularly marked at the present time. The forms which this process takes are often complex. In the United States there has been a twofold movement: the federal government has increased the scope of its authority at the expense of the states, and the states have established a larger degree of control over the local communities. But a more important distinction, possessing a more general validity, is that between legislative, or political, and administrative centralization. Political centralization is accomplished by the enactment by the central legislative body of a detailed code of laws regarding local affairs. Administrative centralization

involves the creation of a hierarchy of officials appointed by the central government who either directly perform the functions of local government or effectively supervise their performance. In Germany, in many instances, centralization is political, state officials being the administrative agents for federal legislation. In the United States, in general, the laws which Congress enacts are administered by federal officials, although much of American centralization takes a political form. In the case of the Eighteenth Amendment the establishing of national control over the manufacture and sale of intoxicants was a significant example of political centralization. But to what extent the federal government shall undertake through its own administrative officials to enforce the amendment and the supporting congressional legislation and to what extent it may leave such enforcement to the states, are questions of administrative centralization.

The basic reason for the trend toward centralization has been the industrial revolution, which has transformed the conditions of modern civilization. The movement of industrial, economic and social organization has been constantly toward larger units, achieving in some instances even an international character. The integration of governmental power is merely a necessary concomitant of these economic and social changes. As the entire nation is psychologically and socially knit into a single community by modern techniques of communication, local political and administrative units appear increasingly ineffective. Moreover, the problems of government today are very numerous and extremely complex. The conception of government as exclusively concerned with the protection of the life and property of the individual has given place to that of the state as a great public service corporation which must provide its citizens with many of the basic utilities of our modern life. In the performance of these new functions a degree and range of technical knowledge is required which local communities are manifestly unable to supply. Modern government demands the services of engineers, chemists, bacteriologists, statisticians, psychiatrists and a host of other technical experts whose employment is quite beyond the capacity of small local communities. The industrial revolution must not, however, be thought of as the sole and exclusive cause for the centralization of government. Many other factors, historical, geographical and sociological, have influ-

enced in varying degrees the extent to which the force of the new industrial economy has been effective in transforming government in particular circumstances.

In France, where government is more highly centralized than in any other constitutional state, the process of centralization was completed before the effects of the industrial revolution were felt. Under the old regime, in spite of a decentralized legal system and the provincial *parlements*, government in local matters was largely under the control of the king's agents. The revolution introduced experiments in local democracy, but these were speedily swept away by Napoleon, who finally unified French law by the establishment of the civil code and set up a system of extreme administrative centralization which has lasted with little change to the present. Such few changes as have occurred have been in the direction of decentralization, and the trend of opinion in France today is definitely toward a larger degree of local autonomy.

The history of centralization in England dates from the passage of the Municipal Corporations Act in 1835. Parliament possesses, of course, unlimited legislative competence, but before this date it had only occasionally concerned itself with local affairs. Local Government was thoroughly decentralized, the only unifying factor of importance being the common law, which was administered through the king's courts. During the last century, however, a large body of statutes regulating local government has been enacted. This legislation has been framed in general terms and has left much more to the discretion of administrative officials than have corresponding state laws in America. The result has been the growth of an elaborate and complex system of administrative control. The functions of local government are not ordinarily performed directly, as in France, by officials of the central government. There exists in England rather a system of supervision which involves the enforcement of standards, the holding to a strict accountability. M. R. Maltbie (*English Local Government of Today*, New York 1897, p. 260) has summarized as follows the instruments by which administrative centralization has been effected in England: grants in aid, that is, national subsidies for local services, conditioned upon the maintenance by local authorities of minimum standards which the national government sets up; administrative orders and regulations issued by the central administration under broad statutory powers; approval or disapproval

by central administrative authorities of acts of local authorities under statutes which require approval for their validity; decisions on appeal by central authorities from decisions of local authorities or in cases in which one party at least is a local authority; the taking over of the administration of local affairs by the central authorities when the local authorities have neglected to perform their duties or have improperly performed them, and the imposition of penalties for maladministration; the conduct of investigations, the publication of reports and the diffusion of information by central authorities with regard to local administration.

In the United States the extreme localism of the colonial period persisted after the winning of independence. In the opening up of the new communities in the West reliance was chiefly upon local institutions of government. The Jacksonian epoch, with its emphasis on popular elections, rotation in office and hostility to bureaucracy, strengthened the centrifugal tendency. But the adoption of the federal constitution and the great series of Supreme Court decisions beginning with *Gibbons v. Ogden* [9 Wheaton 1 (1824)] inaugurated a growth of the federal power at the expense of the states which has been continuous for more than a century. Federal centralization has been chiefly political in character and has taken two forms. The amendments to the constitution, particularly the fourteenth, sixteenth and eighteenth, have greatly extended the scope of federal authority. And through an increasingly broad construction of the constitution the courts have encouraged Congress to legislate upon a wide variety of subjects. The interstate commerce clause has been so interpreted as to permit Congress not only completely to control the instruments and agencies of interstate commerce but under the guise of regulating commerce to establish effectively a supervision over the general welfare of the people. The due process clause of the Fourteenth Amendment has been used by the courts as a means to nullify state legislation, presumably enacted under the state's police power, which does not meet the approval of the judges. Through the power of judicial review there has thus been accomplished not only a centralization of legislative power but a centralized judicial control which is not to be found in any other country. In recent years Congress has appropriated large sums of money as grants in aid to the states to assist them in a number of tasks, including road

building, education, the rehabilitation of ex-soldiers and the care of mothers. Such grants are made contingent upon the states appropriating at least an equal sum and are accompanied by the requirement that certain standards of efficiency shall be maintained in administration.

The enlargement of state authority over the local communities dates in the United States only from the Civil War. In relation to their local communities the American states have not developed the degree of centralization which obtains in Europe. They have, nevertheless, made long strides in the last two generations. The process involves detailed regulation by an elaborate structure of statutory enactments rather than the building up of an administrative machine. The American doctrine of the separation of powers has been interpreted so as to prevent the development of a system of administrative regulations. There is, however, a wide variety of means by which the states are assuming control over local affairs. Any classification must be partial, but the following summary has been suggested (White) as including the most usual devices: advice and information; requirement of reports; inspection without specific power of control; inspection with conditional grant of money; audit of accounts; requirement of prior permission; authoritative review; issuance of orders with power to compel performance; partial or total assumption of activity.

The advantages of centralization have been strongly urged on the ground of efficiency. Certainly many of the functions of modern government cannot be effectively performed except upon a national scale. There is, however, the danger in centralized government of failure to differentiate between communities whose circumstances are widely variant. There is the danger of reducing all government to a dead level of uniformity, where variety would permit useful experimentation and allow adjustments to be made to particular conditions. This has been strongly felt in France where all important regulations emanate from the central government and the local communities have only the most meager share in the determination of their own affairs. Not only is there often great delay in securing the central government's attention to local needs, but decisions are made by bureaucrats, often mere clerks in government departments, who do not possess the information or interest of citizens immediately concerned. The movements for regionalism in France, for devolution in England, for municipal home rule in

the United States, are manifestations of currents in public opinion hostile to these tendencies toward centralized government.

The problem of the best organization of government ought not, however, to be approached merely as one of efficiency. The aims and purposes of government have a direct relation to the form that it should take. If we believe that the fullest possible development of the individual is the primary end of government, it is clear that there is an educational function that must not be neglected and which is not completely performed through the public school system. Participation in politics offers the individual citizen a significant means for self-realization. Yet this is practicable only where there are institutions of local self-government offering not merely to the few but to the many an opportunity for acquiring an experience in public affairs. An effective democracy demands something more than that the qualified voters shall occasionally cast their ballots for national or state representatives. But if the postulates of democracy demand that some effective share in political determinations be provided the ordinary citizen, the question of the most fruitful form of organization is of significance. Such organization should spring from the individual's primary interests and provide the best means for their expression. Neighborhood relationships undoubtedly constitute one set of such primary interests, and institutions of local government afford the opportunity for their realization. But in our present day civilization the most significant relationships are becoming increasingly functional and less and less geographical. Occupational and professional attachments are coming to mean much more than the ties of neighborhood, ward or election district. A vital, continuing interest in politics can be secured only by developing, alongside the institutions of local self-government, a network of institutions and agencies based upon the economic and occupational relationships of individuals.

CEREMONY

PRIMITIVE. Social intercourse among primitive peoples is commonly regulated by fixed patterns. An Australian, for example, treats his mother's brother in a predetermined way distinctive of this particular relationship; and as soon as he discovers that a newcomer, even though he may be from a different tribe, is to be addressed as "maternal uncle" the form of behavior toward him is at once clarified. In Australia, in fact, all individuals with whom social relations are to be maintained at all must be fitted into one or the other of the traditional kinship categories; and a corresponding mode of treatment automatically follows.

Such standardization is often extended to a variety of activities, embracing even what are to us trivial details of the daily routine. A Crow Indian will not simply unwrap his shield: he takes live coals, burns incense, holds his shield

over the fire, raises it a little, lowers it, lifts it higher than before and thus continues until the fourth time, when he raises it high above his head and proceeds to remove the covering. In Uganda the father of a nursing would not set out on a journey without previously jumping over the child's bedding, specially brought out for the purpose by the mother, and then jumping over his wife. Again, Maori fowling returning from their first day's outing were welcomed by the women who waved branches without uttering a sound; a new fire was kindled; the priest recited an incantation over it; and it was only after the priest had taken the first bird snared, pronounced another magical spell and offered the body to the gods that a feast followed and the season was regarded as open. Indeed, at the meal itself the celebrant ate birds cooked in one oven, the fowling those from another and the rest of the people ate birds from still another oven.

In each of these instances the end in view is apparently not sought in consonance with the rationalistic principle of economy but by a devious route. For natives, however, the intervening performances are not trivial delays but elements essential to the success of the undertaking. Any set series of observances not founded in reason, whether overtly associated with religious significance or not, may be designated as ceremonial. A ceremony is not inevitably rooted in religious faith as commonly understood, but it partakes of the solemnity of a religious act. Further, because of the strong primitive tendency to form secondary associations and the overshadowing significance of the supernatural in primitive conditions, a primarily secular observance is very frequently invested with a religious halo. Even when no specific personal deity is linked with the performance the atmosphere is one of supernaturalism and the slightest departure from traditional norms may be fraught, in the native's mind, with catastrophic consequences.

While the essence of ceremonialism probably exists everywhere and is everywhere much the same, its specific manifestations inevitably vary in form and quantity. Naturally, societies which recognize hereditary classes that are hierarchically graded evince a great measure of ceremonial in social behavior. Thus in Tonga, which places a characteristically Polynesian emphasis on pedigrees, a speaker never addressed an assemblage of chiefs before first enumerating the various great personages, who

at least in theory are supposed to follow one another in order of dignity. On these islands the pontiff was regarded as semi-divine and took precedence over the temporal ruler. He was often carried in a litter, any mat or bark cloth he touched became consecrated to his own use, and metaphorical verbiage was employed in speaking to or about him. "The heavens are void" was the phrase used to announce his death. In accordance with Tongan notions of kinship, however, this dignity was outranked by his elder sister and special ceremonial rules obtained between him and her family, as well as between him and the people in general. The pontiff put his head under the foot of the eldest daughter of his elder sister and was obliged to abstain from eating in the presence of all sororal nephews and nieces. But all others were his inferiors: noble officials executing his business kissed his feet, lesser attendants allowed his foot to rest on their heads, and the riff-raff were too plebeian to touch him directly at all and were cured of illness by being rubbed with the bowl in which the great man had washed his hands. Equal elaboration of ceremonial is reported from many Negro kingdoms in Africa, where court procedure often rivaled in intricacy the arrangements fashionable in France in the time of Louis XIV. In Africa, as in Polynesia and in Europe, the etiquette engendered becomes so complex as to encumber the supposed beneficiaries and make equal victims of all classes.

But a fair sociological estimate of ceremonial must envisage other than purely rational motives. When the essentially non-rational nature of human beings is considered, the apparent waste of effort implied in ceremony achieves in truth a kind of economy of its own. That is to say, the individual, instead of being obliged to devise solutions to meet a series of constantly shifting social contingencies, has his course definitely prescribed in its minutest details. He knows precisely what must be done when his son is born, when his daughter has her first menses, when he himself sets out on a war party or returns laden with booty. He need not worry as to the proper mode of behavior, since a sanctioned pattern of conduct exists ready made and is merely to be learned from observation and the precepts of his elders.

Nor is the consequent sense of security the only positive gain. Ceremonial also serves the ends of beauty and is intertwined with specifically aesthetic motives. Thus the repetition of acts according to a mystic number should

probably be linked, as Boas suggests, with the urge for rhythm. Again, the impersonation of supernatural beings, so common in the secret societies of African Negroes and other aborigines, the Plains Indian fiction that the first tree chopped down for the Sun Dance lodge is an enemy and must be struck accordingly, and many similar features are in no wise inevitable exhibitions of the religious impulse, which might be satisfied by an ungarnished prayer, sacrifice or thanksgiving. If ceremonialism develops until a rank growth of extraneous elements completely obscures the alleged end of ritual, it is clearly because other ends assert themselves and rise to ascendancy. Ceremonial, then, even when associated with religion, exists not as a purely religious phenomenon but as an end in itself, set by profound irrational needs of the human soul for social stability and aesthetic satisfaction.

ROBERT H. LOWIE

HISTORICAL. Ceremony is a formal series of acts indicating, usually by traditional methods, an attitude of reverence or a sense of the exceptional importance of an occasion. All ceremonies are valuable as signs of social experience and also as causes of social experience, in the sense that smiling may be a cause of the joy which it is normally supposed to express. Some ceremonies are religious, others are connected with political institutions and still others are forms of social and cultural intercourse. Religious ceremonies may be magical in origin, as in the case of processions with candles or that of the giving of the ring in marriage; and ceremonies of this type seem to retain some of the atmosphere of magic even among highly developed peoples. But magical ceremonies are clearly most powerful in all early stages of civilization, whether the series of acts includes formal words or is a dance form only. The acts which are supposed to affect divine or non-human forces have also psychological effects upon the doers and are often continued because these effects are valued, long after the magic in the acts is discarded or forgotten. Thus certain forms of prayer, cult or worship survive because of their psychological effects.

Kneeling, placing hands palm to palm, bowing and processions are typical elements of ceremony; but a characteristic ceremony is generally a behavior pattern made up of many of these. The ceremonies of Assyrian, Egyptian, Hittite, Greek or Roman civilization may be

regarded as at once religious and political, as we use those words. They bound the community together and heightened the sense of a common life, as in harvest or death ceremonies or in the more sophisticated Athenian ceremonies, the Anthesteria or the Eleusinia. Ceremonies gave a person his place in society, marked his transition through the crises of adolescence or manhood (*rites de passage*) or canalized the emotions at a change of seasons. They have had, therefore, an immense importance in the development of group experience in all types of civilization. The repetition of well recognized behavior patterns gave the first sense of a traditional order in social relationships. Ceremonies gradually elaborated out of many different elements have been the support or even the source of the authority of priest or king and of the sense of common life in any group or people.

Some ceremonies, such as the Eleusinian mysteries, developed out of magical acts and have made men feel a relation to the universe which could not be expressed in doctrine; and some ceremonies have given rise to beliefs as to deity or as to the fate of man at death. Indeed, it was not until very recent times that argument or the inculcation of doctrine was regarded as the most important element either in religion or in political society. The altar is older than the pulpit; the throne older than the tribune. But the pulpit and the tribune do not supply in social experience what was once found in ceremonies. The most influential of all western ceremonies is the mass, in various forms both within and outside the Roman Catholic church—a form of ritual dance by sacred persons, uniting the congregation to themselves by what is called "communion." In its highly developed forms since the fourteenth century, both in the western and in other sections of Christian organization, it has combined pre-Christian "mysteries" with ritual hymns and prayers added in crises, as the *Agnus Dei*. Sacramental ceremonies, for baptism, marriage or extreme unction, continued into the Christian tradition the earliest *rites de passage*, and different seasons had their ceremonies, as at Christmas or Easter. In non-Christian traditions the ceremonies of Judaism and Islam give great prominence to a sacred book; and they are generally more individualistic, as in the case of the Islamic prostrations in prayer. The ceremonies connected with "purification" of women after childbirth or with circumcision seem to relate the individual to the community. In surviving Asiatic religions such as Hinduism,

ceremonies include the ritual slaughter of animals, bathing and turning of prayer wheels, some undertaken by priesthoods, some by devout individuals. Where mediaevalism continues, as in India, there is hardly any distinction between religious ceremonies and social customs embodied in rituals. But in China mediaevalism seems to be less religious, in our sense, and more closely confined to ceremonies of human intercourse or of the crises in experience, such as death. Ancestor worship, as it is called, is largely a matter of ceremony.

In most forms of religion a revival of enthusiasm is marked by an opposition to traditional ceremonies; for it seems to be the habit of those with exceptional religious experience to believe that the traditional forms of action obscure or exhaust the spirit underlying action. In the Protestant Reformation mediaeval ceremonies were regarded as signs of superstition; in the Enlightenment of the eighteenth century ceremonies were regarded as concessions to the needs of the unintelligent. But precisely the same attitude toward ceremony in religion is found in all ages among mystics or individualists. Thus in Islam and Buddhism the same disclaim of ceremony is to be found as in Protestant forms of Christianity. This attitude is a rationalization which has led to a complete misunderstanding of the character of ceremony; for ceremony is never intended to inculcate doctrine. But when it is used to convey non-traditional attitudes or emotions it changes into drama. In the Greek, mediaeval and Chinese drama, ceremonies or ritual forms are used as means of expression for various and new conceptions; but in such cases the distinction between religion and art is not yet established. The ceremonial dance, play, music or painting is not in our sense of the word "art," but more nearly what we call "religion." What ceremony is in earlier undifferentiated stages of civilization is best understood by us if we consider some contemporary social ceremony such as shaking hands; for an effectual ceremony is not an arbitrary symbol, nor is it clearly divisible from the attitude it is supposed by rationalizers to express.

As the earlier phases of civilization pass into a division of functions among different institutions, political authority is reinforced and in some cases made "sacred" by traditional ceremony. It is thus with the religious crowning of a king, a survival of which may be noted in the inauguration of a president. Survivals of the

primitive are to be seen in the military ceremonies of armed forces, presentation of colors and reviews of troops or ships. The prestige of the law is enhanced by the ceremony of court procedure; authoritative assemblies preserve traditional practices, as in the bow toward the speaker's chair in the British House of Commons; diplomacy continues the mannerism of augurs. Especially at important occasions the ceremonies used are traditional; but new rituals can be invented, as in Armistice Day celebrations. An occasion is rendered more impressive by ceremony, as at the drinking of a toast. A person is given greater influence by ceremony, as in the case of a chairman at a meeting.

In social intercourse the most primitive customs of greeting or departure developed into shaking hands in the West or bowing in the East or taking off the hat or clasping hands together. Kissing has a more restricted ceremonial use now than it had in Europe in the fifteenth century; but, on the other hand, some forms of respect, as, for example, men's rising at the entrance of women, tend to spread from "superior" classes to the whole of society. An egalitarian society adopts ceremonies used among equals in a "superior" class. Thus ceremonies become marks of good breeding and indeed do promote a certain graciousness in the contact between persons. Thus also ceremonies pass into etiquette and finally into manners and are, as Confucius recognized, the skeleton bearing up the body of civilization.

The sense of the value of ceremony seems to vary in proportion to the sense of tradition and of mutual dependence. In individualistic societies ceremonies and even manners or traditional forms of politeness are regarded as hypocritical or superficial; and indeed at some stages of social development traditional forms obstruct the tendency to new experience. It is significant that in the section of experience in which ceremony is still strongest—the religious—the social development has been much slower than in politics, industry or art. Ceremonies are like the forms of language, not rationally planned or amenable to reconstruction by analytic reasoning, but preserving a tradition most adequately when most easily adaptable to new situations. The function of ceremony seems to decrease in importance as a community becomes more civilized, because more of social experience can be conveyed and shared by other means. The sense of unity, for example, may be preserved in any people without flag ceremonials if daily life has a common

pattern. Education takes the place of puberty rituals for the entry of a new generation into responsibility for social order. But there is some place for ceremony in any society, just as manners are essential to a democracy even if they have not the same place as in a caste society.

CERNUSCHI, HENRI (1821-96), French-Italian politician and economic pamphleteer. Cernuschi, a lawyer by training, was one of the radical-bourgeois leaders during the "five days" (March 18-22, 1848) in Milan. Later in the Roman assembly he championed a republic and opposed monarchistic centralization under Piedmont. Compromised by his enlistment under Garibaldi's banner and disillusioned he went in 1850 to France, where he engaged in banking and speculation. He gained the favor of Napoleon III and accumulated a fortune which enabled him to retire in 1870. In the meantime he was active also in French politics. By the end of

the sixties he joined the anti-Bonapartist forces, figuring as a frequent contributor to *Le siècle* and financing the republicans opposed to the plebiscite of 1870. For a while he entertained a passing fancy for cooperation and financed with considerable personal loss the cooperative selling of meat. This experience led to the publication of *Illusions des sociétés coopératives* (Paris 1866). He is perhaps best known as "the most ardent, enthusiastic and combative of the bimetallist pamphleteers" (F. A. Walker) and as the inventor of the term bimetallism. His interest in monetary problems was first evidenced in 1865, when he published *Mécanique de l'échange* (Paris) directed against banknotes (or *supposé*), but his multifarious activity in behalf of the bimetallist cause began only a decade later. He came to the United States to testify before the congressional monetary commission in 1877 and served as a delegate of France to the international monetary conference of 1881 and the Paris monetary congress of 1889. He also published a large number of tracts, most of which were translated into English. Orally and in print he fought zealously for international bimetallism based on a 15.5 ratio. Since he insisted on disregarding completely the price trend in the free market for silver he probably did more harm than good to the cause to which he was so quixotically attached.

CERTIORARI at common law is a discretionary prerogative writ issued from a tribunal of superior jurisdiction to one of inferior, commanding the latter to certify to the former a record of its proceedings either for use as evidence or in order that they may be reviewed. Originally the writ of error was apparently merely a special kind of certiorari. After it had developed separate identity as the normal procedure for review of proceedings in inferior law courts of general common law jurisdiction, certiorari as we now know it took shape for review of decisions by tribunals of limited jurisdiction or tribunals "not proceeding according to the course of the common law," at least where no other method of review was specially provided. Thus in England during the eighteenth century many proceedings before justices of the peace in petty criminal cases were re-

moved by certiorari either before or after decision into the court of King's Bench.

Certiorari also came early into use to test the validity of administrative action. The question was first raised in the seventeenth century whether the writ would lie to an administrative agency exercising quasi-judicial functions, and it was at first held that it would not [Ball v. Pattridge, 1 Sid 296 (1666)]. But this decision was soon reversed [Rex v. Inhabitants in Glamorganshire, 1 Ld. Raym. 580 (1700)], and review of quasi-judicial administrative determinations became one of the normal functions of the writ. It was not long, however, before it lost its importance in this respect. The justices of the peace came to be controlled in their administrative capacity through the general Quarter Sessions of the Justices of the Peace; and they also developed the device of voluntarily "stating a case" to the ordinary law courts. Parliament inserted into many administrative statutes clauses forbidding resort to the courts. Although these held that such limitations did not apply where proceedings were vitiated by defects of jurisdiction, this meant no more than that the courts would determine whether the forms of a statute had been observed. The supremacy of Parliament prevented the courts from interfering with administrative agencies which were no less creations of acts of Parliament than the High Courts themselves. In view of this situation it has been regretted that there exists no special system of administrative courts such as that which prevails in continental countries.

In the United States, however, the interpretation of constitutional guaranties by the courts has led to a considerable use of the writ of certiorari to secure judicial review of the exercise of administrative authority, and it has been one of the means of developing whatever administrative law may be said to exist. The leading doctrine has been that certiorari will not lie to review all decisions by administrative agencies but only those which are held to be judicial or quasi-judicial in nature. But state courts have had great difficulty in agreeing as to the types of administrative determinations which meet this test. The doctrine has been sometimes construed so broadly as to cover practically all determinations requiring the exercise of judgment upon facts and the interpretation of law, e.g. a decision by mayor and aldermen to lay out a street [Parks v. Mayor and Aldermen of City of Boston, 8 Pick, 25 Mass. 218 (1829)], the action of

school trustees in uniting or dividing school districts [*Miller v. Trustees*, 88 Ill. 26 (1878); *State ex. rel. Moreland v. Whitford*, 54 Wis. 150 (1882)] and the action of county commissioners in raising the salaries of county employees [*Robinson v. Bd. of Sup. of City and County of Sacramento*, 16 Cal. 208 (1860)]. In New Jersey the writ apparently lies to review municipal ordinances generally [*Christie v. Mayor and Council of City of Bayonne*, 35 Vroom, 64 N. J. L. 191 (1899)]. The meaning of judicial action has not been construed so broadly in all states. It has been held that certiorari will not lie to review the action of a mayor and aldermen in making an appointment under the civil service laws [*Attorney General v. Mayor and Aldermen of Northampton*, 143 Mass. 589 (1887)] or the action of a health board in ordering the cleaning out of a pond [*People ex. rel. Copcutt v. Board of Health of City of Yonkers*, 140 N. Y. 1 (1893)] or cellar [*Hartman v. Wilmington*, 1 Mar., 15 Del. 215 (1894)].

In the case of administrative agencies of the federal government certiorari is practically unavailable because of the holding that administrative action does not become judicial merely because it requires use of discretion [*Dege v. Hitchcock*, 229 U. S. 162 (1912)]. The availability of the writ is further limited by the rule that it will not lie where there exists another method of securing review of the administrative act complained of, e.g. by action at law for damages against the official (*People ex. rel. Copcutt v. Board of Health of City of Yonkers*, *Hartman v. Wilmington*, *supra*). In effect this leads to the same result as the application of the test of the "judicial" nature of administrative acts, since ordinarily an action will not lie against an officer for a judicial or quasi-judicial act. It is clear that certiorari will not lie when the administrative act is of a nature which does not result in a record on which the writ can operate, e.g. an act of summary execution.

What administrative errors the courts will correct by certiorari depends on which of several theories they adopt as to the scope of the writ. It has been widely held that the writ opens up only the question of whether the administrative tribunal exceeded its jurisdiction, and that errors of fact or law made by it within the sphere of its legitimate discretion are not subject to correction on certiorari. When this view is taken with the further doctrine that no error will be corrected which requires for its disclosure a resort to extrinsic evidence not appearing on the face

of the record below, the review is reduced to narrow limits [*Dolan's Appeal*, 108 Pa. St. 564 (1885); the *People ex. rel. Maloney v. Lindbloom*, 182 Ill. 241 (1899)]. It has been held elsewhere, with or without statutory authorization, that review on certiorari extends to all errors of law made by the administrative tribunal [*Morewood v. Hollister* 6 N. Y. 309 (1852)], including the error of making a finding of fact on evidence not sufficient to justify a reasonable man in reaching such a conclusion [*Jackson v. People*, 9 Mich. 111 (1860); *People ex. rel. Cook v. B'd of Police*, 39 N. Y. 506 (1868)]. Substantially the same result is sometimes attained on the jurisdictional theory of review by holding that the existence of jurisdiction may depend on the actual existence of a fact, and that a finding by the administrative body that such fact exists will be reviewed to determine whether there was evidence rationally capable of supporting it: the so-called doctrine of "jurisdictional fact" [*State ex. rel. Milwaukee Medical College v. Chittenden*, 127 Wis. 468 (1906)].

With the increasing importance of administrative action of a substantially judicial nature, such as is involved in the decision of workmen's compensation cases, rate fixing cases for public utility services and the like, certiorari offers the most practicable method of court review in face of the constitutional obstacle, raised under the American view of the doctrine of the separation of power, to a direct appeal from such decisions to the courts. A collateral action at law for damages is either not available to bring such decisions before the courts or, when available, is not adapted to the needs of the case. The effect of direct review is sometimes obtained, as in the federal jurisdiction, by a statutory form of injunction; normally, as in New York, it is achieved by extended use of certiorari.

The employment of certiorari to control inferior courts has also proved especially important in the United States as a statutory means of bringing proceedings of lower courts before the Supreme Court. Since the writ is discretionary in the reviewing court it affords a way of enabling an upper court to sift the business coming before it and to take jurisdiction only of cases of such importance as to justify, in the opinion of the court, the time which their consideration involves. The overburdened docket of the United States Supreme Court has therefore led Congress to prescribe certiorari in an ever increasing number of cases as the method for bringing decisions of lower courts for review be-

fore the Supreme Court. The method was first resorted to in the act of 1891 establishing Circuit Courts of Appeals. Certiorari has since been substituted for the writ of error (which is a writ of right) in additional classes of cases, notably by the act of 1916 which prescribed certiorari as the method of securing review by the Supreme Court of all decisions of state courts except those denying the validity of an exercise of federal authority or affirming the validity of an exercise of state authority which had been challenged as an infringement of the federal constitution or laws. By the act of 1925 certiorari was also made the sole method of appeal to the Supreme Court from decisions of the Court of Appeals of the District of Columbia, and from the Federal Circuit Courts of Appeals except in the single case where a state statute has been challenged as repugnant to the federal constitution and the decision has been against the validity of the statute. This restriction of appeals as of right to the Supreme Court and the substitution of discretionary review by certiorari will, it is hoped, operate to some extent to relieve the pressure on the court by excusing it from considering routine questions of law and allowing it to concentrate its attention on issues which in its opinion are of major importance. The extent to which this hope will be realized must depend upon whether the jurisdictional rules of the court are laid down with such clarity that few needless applications for certiorari will be made. In this the cooperation of the bar is obviously also required. In 1925, following the enactment of the new Judiciary Act, the Supreme Court had to consider the rather large number of 539 petitions for certiorari, and this figure has thus far been exceeded in each subsequent year. It indicates the danger that too much of the time of the Supreme Court may be taken up in deciding, when it can put its time to better advantage.

Federal Appellate Jurisdiction and Procedure (3rd ed. New York 1928) ch. viii; Frankfurter, Felix, and Landis, J. M., *The Business of the Supreme Court* (New York 1927).

CESSION is primarily a term of international law denoting the act, within the limits of that law, of a state in granting to another state rights possessed by the former in respect of territory, as modified by any servitudes resting thereon. Where a state incorporates itself entirely with another state the action goes beyond cession and is not to be so regarded, and where—but only where—an entire state and the governmental organization exercising its sovereignty are conquered by force the action escapes the limits of cession. The term might etymologically be applied to the grant of non-territorial rights but it is not commonly so employed. On the other hand the action cannot be confined to the grant of full sovereignty over territory and hence cannot always be spoken of as a cession of territory itself. Thus there may occur a cession of territorial jurisdiction, or rights of use and exclusion, without full sovereignty or the right of alienation (as in leased areas and concessions).

The power to cede territorial rights depends upon enjoyment of international status by the ceding state (dependencies may not cede) together with prior possession of the rights ceded (internationalized states may not cede). The power to cede may also have been limited or lost entirely by a prior agreement concluded by the sovereign state possessing normal territorial rights (as by the treaty of 1903 between Cuba and the United States). It is also limited slightly by rules of general international law; thus the power of a state to cede a portion of its territory occupied under the law of war by forces of another state is impaired by the somewhat indeterminate status of the sovereignty over that territory.

But the power of a state to cede a portion of its territory is not under international law limited by any requirement for consent, in plebiscite, by the inhabitants thereof. Such consultation of the inhabitants of territory to be ceded is gaining favor as a result of the growth of support for the principle of national self-determination, or government by consent of the governed. In practise, however, it is subject to the exigencies of national policy. By the Treaty of Versailles such action was taken in a number of territories ceded therein (e.g. Schleswig) but not in all (e.g. Alsace-Lorraine).

It does not appear that cession must be accomplished by use of the term itself, or of any particular formula. The action may be given the form of a relinquishment or renunciation. It may be accomplished without written treaty agreement as by tacit cession, under the rule of *uti possidetis* at the end of war; indeed it is such tacit cession which alone converts military conquest into acquisition of title. Agreements for delineation of interstate boundaries may involve cessions of territory not expressly designated as such. Nevertheless the action depends for its completion upon both the consent of the ceding state and that of the grantee (otherwise it would be mere abandonment) together with formal taking possession by the latter. Cession of full sovereignty or of mere territorial jurisdiction may be made in perpetuity or for a period of time, as in cases of leased territory. Partial and temporary surrender of territory has been described as disguised cession, but the true character of the action must be determined in each case by application of the principles stated herein.

The motives which may lead a state to cede territorial rights are not determined by international law. It may take such action for the sake of pecuniary compensation (sale, lease), in consideration of other territorial rights received from the grantee (exchange) or for any other reason which seems sufficient to itself, as, for example, to avoid the expense of reconquest of occupied territory or to avoid military attack and possible conquest.

The effect of cession is to substitute the grantee state in the territorial rights of the ceding state. In view of the rights of these parties to participate in such a transaction under international law, other states are under obligation to recognize this substitution. For example, the United States is bound to recognize the cession of Alsace-Lorraine to France although it is not a party to the Treaty of Versailles. The grantee may now cede the rights acquired by him unless, as in cessions of jurisdiction, the cession has been made without power of alienating them. The rights of the successor state are limited by the law of state succession in general and are frequently limited in treaties of cession themselves. The successor state takes all public property in territory ceded in full sovereignty, unless it is otherwise stipulated by treaty. It inherits, in principle, all public debts attached to the territory ceded or reasonably contracted for its specific benefit, together with a share, pro-

portioned to the capacity of the ceded territory, of the general public debt of the ceding state, provided it has not been contracted for the purpose of resisting the efforts of the grantee to compel the cession by force. Because of the complexity of these standards and the effects of their application the question requires detailed negotiation and settlement in treaty agreement. The public law—constitutional, administrative and criminal—of the ceding state ceases to enjoy authority in the ceded territory where it conflicts with the public law of the grantee state. The latter may now extend its public law to the territory. It may also henceforth modify the law regulating private relations in it, but private rights relating to property, contract or tort remain intact at the time of transfer. The nationals of the ceding state who are resident in the ceded territory become nationals of the grantee state whether so stipulated in the treaty or not; it is not obligatory for the grantee state to allow such individuals to retain their original nationality but this is frequently done (option) subject to any conditions of removal and disposition of property imposed by the grantee state.

CHAADAYEV, PETER YAKOVLEVICH (1794-1856), Russian social philosopher. A member of an old aristocratic family, he served in the army during the Napoleonic wars but resigned from military service in 1820. He participated in the secret revolutionary organizations of his fellow officers of the guard, but in 1821 he left Russia to return only in 1826, after the insurrectionists of December, 1825, had been severely punished for their courage. Early in his career he came under the influence of

de Maistre, Bonald and Ballanche. In the famous letters on the philosophy of history, written in 1829, he declared that Roman Catholicism was the universal form of Christianity and that outside of its discipline no civilization, no continuous progress, was possible. He held that the Russians had handicapped themselves from the start by borrowing Christianity from corrupt Byzantine sources. Russian history exhibits no significant cultural development and the Russian nation, far from representing the synthesis of occidental intellectualism and oriental imaginativeness, is merely uncivilized, barbarous. The publication of the first "philosophical letter" in a Moscow magazine in 1836 provoked a storm of official and popular indignation. The magazine was suppressed, its editor exiled to the far north, the censor dismissed and the author declared mad by order of the czar. The letter was a sharp thrust at the official doctrine of autocracy and Greek orthodox Christianity, which extolled ancient national virtues and proclaimed the superiority of Russia to the nations of the West. In the words of Herzen, it was "a shot of alarm in the darkest night" of Nicholas I's reactionary reign, and earned for Chaadaev the reputation of a revolutionary philosopher. In the "apology of a madman" he attempted a reconciliation with the authorities and the Slavophiles, an emerging group of nationalist thinkers. He renounced his "exaggerations" and admitted that it was possible that in the future Providence might entrust Russia with a "mission" to the world, but he still rejected Slavophile delusions as to the significance of the Russian past. Eventually he decided that his ideas were too far in advance of the times and retired to private life. He received a few friends at home and appeared occasionally in the Moscow literary salons—a handsome and lonely figure looking down with silent irony on the worldly clamor about him.

CHADWICK, EDWIN (1800–90), English sanitary reformer, economist and statistician. Although he was not a physician his continued

insistence on the connection between disease and poverty and on the importance of state regulation of sanitation makes him one of the great figures in the history of public health. He was born at Longsight, Manchester, but his parents moved to London in 1810. He worked his way to the bar by engaging in journalistic activities. Attracting the notice of Jeremy Bentham, he became the philosopher's assistant and lived with him until Bentham's death in 1832. Henceforth he devoted his life to the cause of social reform, and particularly to questions of the poor law and public health. As a member and later as secretary of the Poor Law Commission of 1832 he carried through much important work despite strained official relationships. The introduction of the half time system of education may be traced to Chadwick's report on child labor in factories. Recommendations which he made as the result of an investigation into the causes of epidemic diseases in Whitechapel laid the foundations for an enlightened program of urban sanitation. Chadwick, more than anyone else, was responsible for the formation of the first Board of Health in 1848, and was one of its first members. By its very nature the board infringed on local autonomy and vested interests, and this led to its reconstruction in 1854, when Chadwick "retired" on a pension. For over a generation after his "retirement" he continued his crusade for social reform on a wider basis and with an enthusiasm no longer curbed by official restraint. He achieved a European reputation as a sanitarian. His activities were varied and to them is due much of the progress in poor law reform, water supply, drainage, sewage utilization, army sanitation, tropical hygiene, interments in urban areas, open spaces, school architecture and the education of pauper children.

CHALMERS, THOMAS (1780–1847), Scottish divine, economist and social reformer. Chalmers was one of the first to put forward the theory that poverty is relative to habit, place and time. He stressed the necessity for investigation of the extent and causes of poverty in each case,

as well as for the stimulation of sources of relief within the family and the community, and strongly opposed the whole existing system of taxpaid public outdoor relief, administered on the findings of a mechanical "work house test" of poverty. As head of the parish of St. John in Glasgow he succeeded in obtaining consent to the suspension of the public charity system within the district and substituted an experiment in voluntary poor relief administered by the church and grounded on his theories. The experiment did not last long enough to prove or disprove his contentions, but it started a school of thought, developed by Octavia Hill, Edward Denison and Charles Loch in England and by others in the United States, which eventuated in the Charity Organization movement and finally in the development of the technique of social case work. A parallel movement, known as the "Elberfeld system," had been in progress in north Germany from the middle of the century.

Chalmers accepted the chair of moral philosophy at St. Andrews in 1823 and that of theology at Edinburgh in 1828. These appointments afforded him further opportunity for the elaboration of his social and political theories, which he expounded in his *Political Economy in Connection with the Moral State and Moral Prospects of Society* (2 vols., Glasgow 1832).

In the ecclesiastical history of Scotland Chalmers' contribution was as outstanding as his accomplishments in the field of social reform. He was not only widely known as a great and stirring orator but was the prime mover in the struggle for spiritual autonomy which culminated in the great secession from the Scottish church and the formation in 1843 of the Free Church.

CHAMBER OF DEPUTIES. See LEGISLATIVE ASSEMBLIES.

CHAMBERLAIN, HOUSTON STEWART (1855-1927), German publicist. He was born in England but became a naturalized German citizen and an influential exponent of the mystical mission of the German nation. He received his early education in France and Germany; he then studied various sciences at Geneva; thereafter he steeped himself in the Wagnerian musical, dramatic and metaphysical theories at Dresden. Chamberlain early became a member of Wagner's circle and married the composer's daughter.

His most famous work is his *Die Grundlagen des neunzehnten Jahrhunderts* (2 vols., Munich 1899, 14th ed. 1922; tr. by John Lees, London 1910). Though pseudo-scientific in character and teeming with self-contradictions this work greatly stimulated the rising racial and nationalistic megalomania in pre-war Germany. Chamberlain saw European culture as the composite product of five factors: the art, literature and philosophy of Greece; the law, statecraft and citizenship of Rome; the Christian revelation as rescued from Romanism by the Reformation; the organizing, creative, regenerating genius of the Teutons; and the alien and disrupting influences of Judaism and the Jews. The *Grundlagen* is thus a vast rationalization of European history animated by a sincere but obscure Christolatry, an aristocratic scorn for the masses and a romantic idealization of the Teutonic race as uniquely conceived by Chamberlain. He rejected the findings of the physical anthropologists and devised a "rational anthropology" of his own, so as to include among his "genuine Teutons" brunets like Dante and roundheads like Luther. He did not define race but held that extensive race mixture was the cause of the decline of Rome and of the subsequent millennium of social chaos. He attributed the Renaissance and the Reformation to pure Teutonic leadership; and he despaired of the European future unless the racial purity of the Teutons could be restored and express itself in an uncontaminated Teutonic religion.

Entz (New York 1928) ch. viii; Schroeder, L. von, *Houston Stewart Chamberlain* (Munich 1918).

CHAMBERLAIN, JOSEPH (1836–1914), English statesman. Chamberlain came of an old established manufacturing family. At the age of eighteen he began a twenty-year association with his uncle's screw factory in Birmingham. He retired in 1874, was elected to the House as a Liberal in 1876 and within four years entered the cabinet. From the beginning his political career diverged from that of most Liberals of the manufacturing class in the direction of social reformism decidedly opposed to laissez faire notions. He attacked the established church, demanded liberalized education and land reform, sponsored sanitation and civic planning projects and successfully championed municipal ownership of public utilities in Birmingham. His views were expounded in terms of natural rights doctrine and a theory of the obligation of private property to pay ransom for its security.

In foreign affairs Chamberlain was an apostle of territorial expansion. He fought Irish home rule, proposing instead various combinations of local autonomy and imperial federation, and finally seceded from his party because of differences on this question. As colonial secretary in Lord Salisbury's new Liberal Unionist government of 1895 Chamberlain renovated the administrative machinery of the Colonial Office and enthusiastically set out to extend the empire and to promote trade within it. In matters affecting British interests in Egypt, Uganda, Samoa, the Gold Coast and Lagos and in the events culminating in the Boer War he constantly kept to the fore his program of expansion and consolidation. His policy of reconciliation with the defeated Boers was a link in the chain to bind to Great Britain her dependencies and possessions. The creation of a department of agriculture for the West Indies, the sponsoring of tropical health work and similar enterprises had the same motivation.

Chamberlain, who had seen Birmingham's steel industry badly hit by the dumping tactics

of the protected manufacturers of the United States and Germany, gradually abandoned pure Manchesterism for a neomercantilist position. He argued that social progress in Great Britain depended on imperial prosperity, and that prosperity in turn depended on the development of trade within the empire, in the direction of self-sufficiency. His solution of imperial economic problems was the abandonment of free trade and the adoption of reciprocal preference arrangements among the constituent parts of the empire. Three years of agitation with the support of the Tariff Reform League failed to teach the electorate "to think imperially," although later some reciprocal concessions were made.

Chamberlain hoped that commercial and fiscal unity would constitute the basis for political federation. He proposed to the colonial conferences of 1897 and 1902 the establishment of a "great Council of Empire" of advisory character which might develop into that federal council with executive and some legislative power "to which we must always look forward as our ultimate ideal." Chamberlain's proposals met with little support at the time, and recent developments have revealed a tendency toward the substitution of local national rather than imperial attitudes in place of the waning colonial attitudes of the self-governing dominions.

Eight years before his death Chamberlain suffered an attack of aphasia which cut short his career.

CHAMBERS OF AGRICULTURE. Chambers of agriculture originated in Germany, where they have attained their greatest development. The oldest existing chamber was created in 1824 in the free and Hanseatic city of Bremen. The movement in its present form had its beginning with the Prussian law of 1894. Since the World War legislation regarding these organizations has been substantially modified and extended. In 1920 both Austria and Hungary adopted measures establishing chambers of agriculture. While their legal structures are somewhat different in the three countries, their general purposes and scope of activities are

similar. The analysis below applies largely to the forty-one chambers in Germany.

Chambers of agriculture are a unique mixture of the private and the official in one organization. They are official in that they are supported in part by a land tax levied upon all farmers of the district and collected by the revenue officers of the state. The minister of agriculture may reject the budgets of the chambers if he considers them excessive. The legal intent is that the chambers shall work in close harmony with state and federal officials, who are in turn instructed by law to consult with the chambers in the formulation of agricultural policy. On the other hand, these organizations are free agricultural associations. Their members are elected solely by the agricultural classes. Each chamber elects its own officers. Perhaps the greatest essential difference between the chambers of Germany as compared with those of Austria and Hungary is that the latter are subjected to a greater degree of governmental control, especially in Hungary.

The members of each chamber are elected by secret ballot on the basis of proportional representation. While eligibility for voting differs, the qualifications in Prussia may be taken as typical. "Every German without distinction of sex has a right to vote, who has completed his or her twentieth year, who enjoys civil rights, and has been engaged for at least a year in agriculture as a principal occupation, either as owner, holder in usufruct, or tenant of lands used for agriculture or forestry in Prussian territory. . . . On an equal footing with owners, holders in usufruct, and tenants, are considered the wives of such persons working with them on the farms." All persons qualified for voting who have reached their twenty-fifth year and have lived continuously in the district of their chamber for at least one year are eligible for election. Hence the elected members are drawn entirely from those engaged in farming. The chambers are permitted, however, to choose a limited number of members in addition to those elected, in order to enlist the services of agricultural scientists and others not engaged in farming. The number of members varies with the different chambers. On January 1, 1929, it ranged from eleven in Sigmaringen to one hundred and twenty-three for Saxony. In Baden, for example, the law specifies that thirty-six members shall be elected as representatives of the farmers and eight as representatives of agricultural labor. Twelve additional members

are co-opted by the chambers; of these four must represent forestry, one market gardening and one labor, and the remaining six must be persons of repute and of experience in stock breeding, arable farming, viticulture, fruit growing and cooperation.

The general purpose of the chambers is to "safeguard the rights and promote the welfare of agriculture." The following summary of the functions enumerated in the Prussian law illustrates the wide scope and general nature of their mandates: to safeguard agricultural interests, economic, commercial and fiscal; to increase agricultural production in all its forms; to collaborate with state institutions for agricultural purposes; to preserve existing institutions and to create new institutions designed to improve the conditions of the rural classes; to promote the economic disposal of agricultural products; to collaborate in the placing of farm labor; and to assist in the promotion and extension of agricultural education and research.

The chambers specialize in the technical aspects of agriculture as contrasted with the buying and selling activities of the cooperative associations or with the political programs of such groups as the Imperial Land Alliance or the Association of German Farmers' Unions. They work in close harmony with the other organized agricultural groups. The following table of expenditures of the Brandenburg chamber for the year 1927-28 indicates the principal lines of activity followed:

ACTIVITIES	EXPENDITURES	
	ABSOLUTE	PERCENT
Research, teaching and extension	\$ 544,885	31
Veterinary purposes	148,400	8
Promotion of:		
Livestock breeding	309,965	18
Fisheries	319	—
Forestry	65,032	4
Horticulture	86,030	5
Agricultural societies	236,339	13
Administration and other purposes	361,161	21
Total	\$1,752,131	100

The Brandenburg chamber, which is one of the largest in Germany, has a staff of more than four hundred people. It maintains laboratories, conducts fertilizer, feed and seed tests, operates experimental farms and agricultural schools.

The following figures on the receipts of the

Chambers of Agriculture - - Chambers of Commerce 325

Brandenburg chamber for the year 1927-28 may be taken as a reliable indication of income sources:

SOURCE OF INCOME	RECEIPTS	
	ABSOLUTE	PERCENT
State subsidies	\$ 167,206	10
Other subsidies, including provincial and communal	131,732	8
Taxes	441,829	25
Other receipts, principally for services rendered	1,011,364	57
Total	\$1,752,131	

The central national body is the German Council of Agriculture composed of representatives from the local and state chambers. It looks after those interests of the chambers in which the federal government can and does play a part, and is occupied chiefly with questions of policy. Its activities are divided into five parts: general policies, education and credit; taxation; foreign trade, tariffs and marketing; press and publications; and business management.

CHAMBERS OF COMMERCE are essentially institutions for the representation of the vocational and sometimes also civic interests of business men organized on a regional basis. They undertake to develop and facilitate commerce through technical, administrative and promotional work and to influence government organs and officials to give favorable consideration to commercial interests; and they pursue, in the United States, also civic objectives, reflecting the business man's point of view. In the United States and the British Empire such institutions are sometimes, although with decreasing frequency, known as boards of trade, commercial clubs, merchants' associations, boards of commerce and associations of commerce. In

other countries the equivalent term for "chamber of commerce" is generally employed, such as *chambre de commerce*, *Handelskammer*, *camera di commercio*, *kamer van koophandel* and *cámara de comercio*.

Associations of merchants for somewhat similar purposes existed at least as early as the Roman Empire, and the mediaeval guilds and corporations were historical prototypes of the chamber of commerce, but the *Chambre de Commerce* of Marseille, founded in 1599, was the first such organization bearing the modern name. The type of chamber generally created by law in France during the eighteenth century was introduced into the Rhineland by Napoleon and is found today in France, Germany, Italy, Spain, the Austro-Hungarian successor states, Holland, Denmark, China, Japan and Brazil. The Jersey chamber in England and the New York chamber in America were both established, although independently of each other, in 1768. By 1801 New York, Philadelphia, Charleston and New Haven had chambers; by 1858 there were thirty, although some of these had only an ephemeral existence. In 1880 England had less than forty chambers. During the last quarter of the nineteenth century, however, the institution became more popular and in the last thirty years it has spread rapidly, established itself firmly and increased the scope of its work. Today there are 172 chambers in England and approximately two thousand in the United States. More than 2,000,000 individuals are affiliated in several thousand chambers throughout the world, 920,000 being affiliated with the United States Chamber of Commerce through 1655 organizations.

The growth of chambers of commerce has been a concomitant of the expansion of commerce. The increased complexity of problems confronting the merchant class and the growing consciousness of mutual interests underlying competitive activities created the desire for a means of collective action for the solution of those problems and the furthering of those interests. The paternalistic states of continental Europe produced the official type of chamber of commerce, established by law and subject to government control, and supported by government subsidy or special taxes levied on a membership composed of all merchants of a particular class within the district covered. The Anglo-American type of chamber, on the other hand, was a creation of private initiative and is still a purely private and voluntary institution without

financial resources except membership dues and small incidental earnings.

The organization of a chamber of commerce consists usually of a board of directors and a president. In the continental type the president is generally a nominal head and the directing board alone is known as the chamber. Work is accomplished through committees and bureaus under the general supervision of a paid secretary, who formulates the program and manages finances. His task has become highly professionalized and in continental countries is regarded as public service of a reputable character, attracting, especially in Germany, where state pensions are provided, many economists and students of international trade. In the United States, however, chambers of commerce, forced by their lack of official support and financial security to resort to constant membership drives and oftentimes to high pressure town boosting campaigns, have tended on the whole to attract as secretaries publicity or promotion men adept in concocting optimistic propaganda but with slight equipment to handle complicated problems of trade development. As a result chamber work in this country is on the whole unscientific. For example, repeated cases of economic distress have resulted from the inevitable failure of industries attracted by publicity and special concessions to locate in unsuitable towns. The secretaries of American chambers have a national organization and a training school which is endeavoring to raise the standards of the profession.

Federation of chambers of commerce has taken place on a regional basis in most countries. The French national chamber is only a few years younger than the Marseille chamber. The German national federation (Handelstag) is a descendant of a seventeenth century body. Both the French and the German institutions have an official status. A National Board of Trade was organized in the United States in 1868 "especially in order to secure the proper consideration of questions pertaining to the financial, commercial and industrial interests of the country. . . ." In 1912 it was superseded by the Chamber of Commerce of the United States, an organization formed with government encouragement. Its stated aims were to promote foreign trade, business cooperation, standardization of methods and the raising of business ethics. The dynamic force back of the organization at its inception was the widespread fear of the contemporary trend toward government

regulation of business. The membership of this chamber is composed of local chambers, which pay dues equivalent to about one half of one percent of their income and have the right to vote, and of individuals who pay a fixed sum, receive all the chamber's services but may not vote. The chamber is governed by a directorate representing both districts and interests. It issues a magazine, the *Nation's Business*, and maintains a large technical staff in its building at Washington. There are also national chambers in England, Belgium, Switzerland, Brazil, Cuba, Australia and other countries. In some of the federal countries state chambers of commerce function in state affairs much as the local and federal chambers do in their fields.

The functions of chambers fall into two divisions. On the one hand, they perform a variety of technical and administrative services for the members and the commercial class in general. On the other, they attempt to interpret to the government the attitudes and desires of the commercial class and to influence the government favorably.

The technical and administrative services of continental chambers include: the administration, and sometimes the ownership, of stock exchanges, employment bureaus, docks, warehouses, weighing and testing machinery, commercial schools, museums and libraries; the preparation of trade reports; the issuing of export certificates and certificates of origin; and the appointment of experts, inspectors, surveyors, accountants and commercial arbitrators. American and English chambers render a more limited technical service. They concern themselves with improving transportation; lowering freight rates; providing information on traffic routes, markets, credit standing, methods of packing for foreign shipping and general trade conditions; collecting claims; commercial arbitration; provision of labor supply; standardizing of methods; and general publicity work such as advertising home products, enticing tourists and conducting expositions, special sales, "get acquainted" trips. A number of the larger chambers both in Europe and America maintain research bureaus. But inasmuch as their work is published only with the approval of the directors it cannot generally be regarded as unbiased scientific research.

The second great phase of chamber of commerce work is its representation of the commercial class before the government. The continental type of chamber has formal contacts with

government instrumentalities and officials. These contacts may range from representation on a legislative council, as in the Straits Settlements, or on other official bodies, such as the Bavarian Railway Council, to the more common arrangements for receiving from the chambers reports, advice and proposals for legislation. This official relationship, together with the fact of compulsory membership, which automatically makes the continental chamber a representative body, has won for it high prestige and great influence. The Anglo-American type of chamber makes its approach to the government unofficially and by means of the ordinary lobbying technique of general publicity, political pressure, public hearings and the like. Such action, whether official or unofficial, is generally directed at killing unfavorable, or passing favorable, laws on budget, tariff, bankruptcy, trusts, banks, itinerant merchants, labor conditions and hours, store hours, child labor and similar questions. Commercial legislation of the first importance has been effected by the activities of chambers of commerce. Not only has their influence been brought to bear in inducing the United States government to undertake more and more technical and research investigations of a type beneficial to business men, but it has also contributed largely to the passage of the United States Transportation Act (1920) and the Budget Act (1921), to a revision of postal rates (1928) and to the defeat of a proposed quota for Mexican immigration (1928).

Such activities classify chambers of commerce with numerous other pressure groups of the modern democratic state functioning outside the ordinary legislature. In fact the chambers have been viewed by some as the germ of a system of functional representation, and their official status in such countries as Germany and Austria, where they contribute materially to the making of government decisions on all business matters and where they are counterweighted by official labor bodies of similar character, is pointed to as foreshadowing developments in this direction. Even in the United States the national chamber, with seventeen members sitting in Congress, constitutes an unofficial functional constituency of the federal legislature.

Although their membership is drawn from the commercial and employer class and although they devote themselves primarily to the interests of that class, the chambers in the United States maintain that they represent the entire com-

munity. They launch elaborate civic programs which they believe to be beneficial, from a business man's point of view, to society. These programs include municipal reform and reorganization of the state government, road and bridge construction, public hygiene, sanitation, water supply, park developments, traffic control, regional and town planning and conservation and development of natural resources. They insist upon better methods of public budgeting, accounting and financing, and a generally more businesslike procedure in the conduct of the public business. On the other hand they oppose all civic action which they regard from a business man's point of view as against public interest. They view proposals for the acquisition by the state or municipality of a gas, electric light or power plant or a street railway or for the promotion of model housing by a state or municipal subsidy as "socialistic attempts to put government into business," and proposals to use excess condemnation in the financing of public improvements as schemes violating the rights of private property. They are inclined to regard proposals for the establishment of a chain of federal, state and municipal employment bureaus as signs of the further multiplication of an already excessively large bureaucracy and of further interference with business; and proposals for the establishment by the state of a system of old age pensions as "paternalistic schemes that will discourage thrift."

The chambers are opposed to all social movements considered inimical to commercial interests. They were prominently identified with post-war campaigns against liberals, radicals and union labor. The Chamber of Commerce of the United States has officially endorsed the doctrine of individual initiative without any qualification except the urging of government services for business, and it has opposed government operation, ownership or even energetic regulation of business. It endorsed without qualification the so-called "open shop" and opposed federal regulation of child labor. One Pennsylvania chamber has attacked as "vicious" a law prohibiting night work in glass factories for children between fourteen and sixteen. Standing for progress in all matters calculated, according to the understanding of the average business man, to advance the interests of the business class the chambers are inclined to assume a negative attitude in all matters not calculated, according to such understanding, to accomplish that result, and to op-

nose militantly any proposal of a change in the present system of distribution of wealth and power between the different classes of society. On the whole the chambers seem to be reservoirs of ultraconservatism in modern society.

As in all discussions of pressure groups the question must be answered as to how accurately the chambers reflect the views and interests of their members. The usual response to referenda conducted by the Chamber of Commerce of the United States among its members to determine opinion as a basis for lobbying activities involves not more than 58 percent of the total membership. The questions are answered by organization members and often by organization secretaries, who may or may not consult their group before replying. In either case the matter is given only cursory consideration. Furthermore, the questions are frequently framed in the referendum in such a way that there can be little doubt in the mind of the representative of the average chamber as to how he should vote upon them. The secretary of a local chamber ordinarily draws up resolutions which obtain automatic endorsement. Thus the members approve opinions not only on commercial topics but also on such general questions as government ownership, compulsory military training, the teaching of evolution and international peace—opinions which bear the mark of amateurishness and gross ignorance and which sometimes may be contrary to the real interests of the members. The same superficiality usually characterizes other actions of the chambers. Committee reports are drawn up hastily, usually by the secretary of the organization, whose business it is to see that no action is recommended which may stir up a controversy and cause a loss of members. Actions are taken which are unobjectionable or which, it is known, will be popular with the members. Even if these difficulties were solved by providing for a more thorough consideration and debate of questions and reports and by canvassing more accurately the whole membership the fact would remain that chambers, especially in America, represent elements which, measured by the criteria of functional representation, constitute more than a single class. Only a few places (e.g. Hamburg and Bremen) have separated wholesale from retail merchants, and the American chamber includes, in addition to these, manufacturers, mine owners, transportation officials, professional men and real estate

dealers, groups whose special interests may deflect the chamber from a purely mercantile policy.

Two modern developments of the chamber of commerce warrant special attention. As an outgrowth of modern international trade have come the "foreign" chambers of commerce which, beginning in Hongkong in 1861, have been established by alien merchants to stimulate trade with the mother country, a motive usually expressed as a desire to promote reciprocal exchange. Such organizations are common in European and American capitals. In some non-Christian countries all the European merchants have joined a common chamber. American and English foreign chambers are private organizations; some, like the French, are semi-official, partially subsidized and controlled by the home government. Some states desiring to discourage such chambers in their own territory try to prevent their nationals abroad from forming them. Others have found them useful as part of the machinery of economic and political imperialism in backward countries; they spread the home culture, influence and propaganda, supply information to the home government and on occasion serve as convenient mouthpieces to raise the cry for intervention.

Finally, there is an International Chamber of Commerce, established in 1920 to replace the International Congress of Chambers of Commerce which had been held from time to time before the war but which never had any permanent organization. The International Chamber aims "to include all the economic factors of international business . . . to secure effective and consistent action . . . improving the conditions of business between nations and to encourage international and better understanding. . . ." A permanent staff functions in Paris, national committees are active in the countries whose national federations are members, and the chamber's general congress meets biennially. It maintains a Court of Commercial Arbitration and publishes a magazine, *World Trade*. The chamber is chiefly concerned with problems of double taxation, export credits, foreign exchange, standardization of business forms, customs regulations and statistical forms improvement of transportation and postal systems, port facilities, neutrality of the seas, calendar reform, international expositions and, in a vague and general way, world peace.

CHAMPLAIN, SAMUEL DE (1567-1635), French geographer and colonist. After a voyage to Spanish America and several years spent in assisting the attempt to found a colony on the Bay of Fundy, during which he explored and mapped the adjacent coast as far south as Cape Cod, he founded Quebec in the year 1608 and so began the colony of New France. He spent the remainder of his life in the nurture of this infant colony. Champlain had to overcome the severest of physical obstacles, the lack of support from France itself, the lure of the fur trade which discouraged land settlement, the perils from the Iroquois, the controversy between Catholic and Protestant, the menace of foreign war. Company after company was founded to promote settlement, but not until 1627 did Richelieu's newly founded Company of New France seriously take up the task. Its first attempt failed, for in 1629 the English captured Quebec and held it for three years. Before Champlain died, however, the colony, although tiny and weak, had struck its roots into the soil.

Scarcely less important were Champlain's achievements as explorer and geographer. After founding Quebec he made three important voyages of discovery: to Lake Champlain in 1609, up the Ottawa in 1613 and to Lake Huron

in 1615-16. Of these voyages he wrote accounts, accompanied by maps which contributed greatly to the increase of geographical knowledge of the New World.

CHAMPOILLION, JEAN FRANÇOIS (1790-1832), French Egyptologist. Champollion, who became known later as the founder of Egyptology, devoted his early youth to the study of Egyptian languages and history. In 1809 he was appointed professor of history at Grenoble; from there he went to Paris to study Egyptian antiquities. With the Rosetta stone as the key he deciphered the complex Egyptian writing, which he discovered consisted of three elements, figurative, ideographic and alphabetic. He explained the hieroglyphic alphabet in his *Lettre à M. Dacier relative à l'alphabet des hiéroglyphes phonétiques* (Paris 1822) and further elaborated it in the *Précis du système hiéroglyphique* (2 vols., Paris 1824, 2nd ed. 1828).

Following his deciphering the hieroglyphic alphabet he was appointed keeper of Egyptian antiquities at the Louvre; he directed a scientific expedition to Egypt; he was made a member of the Academy of Inscriptions and in 1831 a chair of Egyptology was created for him at the Collège de France.

After Champollion's death some of his most important manuscripts, including *Monuments de l'Égypte et de la Nubie* (4 vols., Paris 1835-45), *Grammaire égyptienne* (Paris 1836) and *Dictionnaire égyptien* (Paris 1841), were edited by his brother. These works greatly contributed toward laying the foundation for later Egyptological discoveries.

CHANCERY. *See* EQUITY.

CHANG CHIH-TUNG (1837-1909), Chinese statesman. He entered public life in 1863, and in 1884 as viceroy in Kwangtung during the Franco-Chinese War he argued against China's responsibility to France for damages to Chinese Christians. In 1898, after the Japanese war had awakened and perplexed Chinese opinion, he suddenly attained leadership of the moderate liberals by his brilliant, widely read and influential essay, *Learn* (abr. tr. by S. I. Woodbridge as *China's Only Hope*, New York 1900), in which he urged China to avoid India's fate and to follow Japan's example by learning from the West how to develop the elements which gave those nations strength: governmental efficiency, modern armies and navies, factories, mines, railways, schools, the press. Some of these he had already introduced in his domain of Hukwang. Because of his conscientious opposition to democratic institutions and his belief that the Confucian foundations of Chinese statecraft should be conserved by more complete centralization under the Manchu dynasty, he refused to join K'ang Yu-wei and the emperor in their program of drastic reforms (1898). When the empress dowager's coup and the Boxer reaction resulted from the premature reform decrees he begged the empress dowager to withhold support from the Boxers and during their fanatical outbreak he maintained order and protected foreigners in central China. Although Chang continued in office after this disastrous rebellion his mild progressiveness—now no greater than that of the court—appeared as conservatism, since radicalism and even revolution were being preached by Dr. Sun and by growing numbers of students who had returned from Japan.

CHANG HSUEH-CH'ENG (Shih-chai) (1738-1801), Chinese historian. He was born in Kuei-chi, Chekiang province, and was the most creative writer on historical method and on the theory of history that China had produced since the time of Liu Chih-chi (661-721 A.D.). His two outstanding works are the *Wen Shih T'ung I* (General interpretation of literature and history) and the *Chiao Ch'ou T'ung I* (Principles of textual criticism).

In his treatment of the origin and technique of Chinese historical scholarship Chang Hsueh-

ch'eng advocated, far in advance of his time, genetic view of history in which the fixed categories of former historians are discarded and the form adapted to the materials rather than the materials to the form. For this reason he favored the topical rather than the chronological or dynastic treatment of history. He held that the qualifications of a great historian are talent, training, sound judgment and historical veracity and that a true history should show understanding, be faithful to the facts and have literary form. He believed, moreover, that not only the canonical books but all records of the past, such as biographies, edicts, laws, official documents, should be considered as materials for the historian, thus greatly enlarging the scope of Chinese history. In urging the establishment of centrally located libraries, under government supervision, where the rare materials of history could be preserved, classified, collated and conveniently indexed, and so made available to those who wish to ascertain the facts, he anticipated the public libraries of our day. He advocated a radical revision of the categories of local histories and stressed their importance to Chinese historians at a time when these were not regarded as works of history.

CHANGE, SOCIAL. As a term carrying a definite scientific connotation, social change has come into use only recently. The concept bears a certain relation to the somewhat earlier ones, social evolution and progress. Social evolution had come to be identified fairly closely with the dogma of inevitable successive stages of development based on biological determinants; and progress usually implied a faith or borrowed standards from current morals. The need for a term free from dogmatic or moral implications explains the present day preference for the expression social change, which suggests to most readers objective description and an absence of implied values.

A first point of difference between theories of social change and the conventional theories of social evolution turns on the question, what is it that changes? Climate changes but slowly and over long periods of time. So, too, the greater proportion of a race of men appears to remain pretty much the same, although this point is still

disputed. During the historical period changes in climate or in inherited biological nature are at least slight in comparison with other changes, so slight that they are generally neglected as causal factors in the social changes of history.

What does change in culture, or the social heritage. Culture is that part of our environment for which animals living in the wild state do not have a counterpart, although some wild animals have the crude beginning of a culture. Some factors in culture do indeed show great capacity for maintaining themselves unchanged, but the system of culture as a whole may exhibit almost revolutionary changes, even within a single generation.

The key to change may be sought in invention. The word as here used means any new element in culture—a much broader meaning than the term commonly conveys. For culture as a whole the force making for change is the creation of an invention. For a particular culture area social change is due to an invention either made in that area or else imported into it. To understand social change it is necessary to know how inventions are made and how they are diffused.

Inventions are combinations of existing elements of a culture into a new form, as, for instance, the telegraph. Not all of the elements in question are material elements; some of them may be principles or ideas. There is at any one time a current stock of ideas just as there is a current stock of material objects. Thus there is the idea of rapid communication which is an element in the invention of the telegraph. Ideas that are pressed on the attention are one phase of demand or "necessity," long recognized as the mother of invention. Demand or necessity naturally cannot produce inventions unless there are in existence the materials out of which the inventions can be made. Primitive man had serious need of scientific medicine but made few discoveries in this field. There seems to be sufficient demand or necessity at all times to produce social change.

Inventions, being useful, tend to accumulate. They sometimes result in the substitution of a new form for an old one. If the old form is completely supplanted there has been no accumulation in this particular instance. This may often happen in a restricted area. The grain cradle does not persist alongside of the binder, nor do the bow and arrow alongside of the rifle. It is less frequently the case that a new form substitutes itself for the old throughout the world.

Most forms ever in use are still in use somewhere. There are still culture areas in which the neolithic technique persists.

The tendency of inventions to accumulate results in an increase in the existing cultural elements which may go to make a new invention, and hence an increase in inventions. The curve of growth of inventions exhibits a similarity to the exponential curve. Accumulation of inventions means not only a greater amount of social change but a more rapid social change. No doubt other factors besides the mere drive of accumulated inventions enter into the group of forces making for new inventions. Necessity is one such factor. One may refer to the part played by necessity in war time in evoking the invention of counter-weapons for each new arm put into successful operation. In the general case, however, demand or need may be taken for granted.

It is the net addition of small elements to culture that makes invention a process. Because this process is continuous social change is continuous. It is believed that in very early times social changes were irregular because of the rareness of invention. In a particular series of inventions such as fire making this may have been true. When, however, a large number of such series are in process simultaneously social changes are more numerous, more frequent and perhaps more regular. Irregularities in the process of social change are also due to the fact that not all new elements of culture or inventions are of the same potency in precipitating changes. Such inventions as the electric motor, the incandescent light, the moving picture and the radio have vastly more capacity to precipitate social change than the flashlight or the cigarette lighter. But whatever irregularities in social change may follow from the casual occurrence of significant inventions, it appears extremely improbable that such irregularities would form a series that could properly be described as a cycle.

What has given rise to the belief that social change proceeds by cycles is the fact that there are certain historical periods of great social change with stretches of time characterized by less activity between them. Such periods, for instance, are the Renaissance and the industrial revolution. These great changes may be due to many factors, as for instance the recovery of classical learning, the opening of new trade routes or new lands for exploitation, or new sources of power of wide application, as for

example the steam engine. In such cases we may say that inventions appear in extraordinary clusters, and we should naturally expect social change to proceed at an unprecedented rate. It is also probably true that the historical perspective exaggerates these changes. History contrasts the Renaissance and the Dark Ages only with respect to art, learning and social organization, but these taken together compose only a small fraction of culture. It is not generally known that there were many important mechanical inventions during the Dark Ages. History indicates periods of quiescence between periods of rapid social change, but this too may be largely a matter of perspective. Granting, however, occasional great irregularities, we should not lose sight of the principle that social change in advanced societies is normally a continuous and even fairly regular process.

Social changes are more numerous now than formerly because the cultural elements are so much more numerous. Although there are other reasons, this is perhaps the outstanding one. Social change among the Eskimos is slow not, it is thought, because they are low in mental ability but because they do not have sufficiently numerous cultural elements to operate with.

Rates of social change differ not only according to the stage of social development but also for the several parts of our social heritage. This heritage may be classified for the present purpose under material objects (together with the immediate processes of their production and use) and non-material culture including social organization, science, art, philosophy, music, painting, sculpture, literature, religion, morals, customs and the like. Observation not, however, established by statistics seems to show the most rapid changes at the present time in material culture and in science and less rapid and less numerous changes in other aspects of non-material culture. It also appears that the accumulative process is at present more active in natural science and material culture. Thus the material and natural scientific part of the cultural base appears to be growing larger more rapidly than the non-material part. If we are justified in assuming a functional relationship between the several parts of the cultural base and the future rate of social change we may forecast increasingly rapid changes in material culture.

If the parts of culture which change at unequal rates were uncorrelated, as the water at the surface and at the bottom of a flowing stream, there would be no problem. But many of the

parts of our social heritage, somewhat like an intricate machine, are closely correlated, and when one part changes the correlated part also needs to be changed. Thus science and religion are correlated, and when scientific discoveries bring new ideas concerning such items as life after death, the immaculate conception, the age of the earth and the early history of man, religion tends to change accordingly, but somewhat later. So also family life adjusts itself to the factory after a lag. A change in the family or in religion may originate from within or it may be forced upon family or church by inventions or discoveries in some other part of culture. Many changes in social life are thus precipitated by changes in the mechanical or scientific culture. Thus the preservation of food in tins or the invention of contraceptives influences the position of woman. At the present time a very large number of initial changes are occurring in the vast volume of material culture, and relatively few changes take their origin from within social life as such. At the present time it is the social life that is compelled to adjust itself to changes in material culture. It is entirely conceivable that the conditions might be reversed and the material culture might be compelled to adjust itself to changes originating in social life. It might be difficult to adduce examples covering a wide culture area, but in limited areas subject to invasion by a foreign culture it is quite possible that non-material culture will be absorbed first and that material culture will be forced to undergo a process of adaptation. So new ideas, new habits, new philosophies, were diffused into the Orient and became precipitators of change as truly as were tools and mechanical devices.

When we pass from culture as a whole to the culture of a particular country we encounter many factors affecting the rate of social change. Most changes are introduced into the particular locality from without. The rate of change is accordingly very slow in isolated islands, deserts or mountainous regions, where there is little intrusion of change from the outside. It would be still slower if change had to wait wholly on invention or discovery within the particular area.

There are various obstacles to the penetration of the factors of social change into a country, even though the barrier of isolation is broken down. Many factors of change are great clusters of inventions. The adoption of the horse meant the adoption of a horse culture. The adoption of the automobile compels the provision of the

services of mechanics, steel, cotton, rubber, gasoline, good roads, filling stations and hundreds of other correlated factors. The area adopting a new factor in culture must have the correlated elements necessary to its utilization. Similarly the successful importation of ideas such as democracy or theories of natural selection is likewise dependent on the presence in society of correlated ideas, which are as real as concrete objects. Some ethnologists claim that the diffusion of material culture is more easily accomplished than the diffusion of non-material culture, but there are certainly many exceptions.

That social changes do not follow immediately upon invention is due not merely to the fact that it takes time for an invention to become known. There are positive resistances to be overcome. Sometimes these take the form of ingrained habits. This seems to be the chief obstacle to the introduction of simplified spelling, the metric system and the thirteen-month calendar. The tenacity of personal habits also accounts for the resistance to changes in language and to the substitution of science for superstition or ignorant tradition in medicine, diet and even agriculture. Often an invention affects only one part of an extensive complex; its application would involve numerous inconvenient and expensive adaptations. The standard gauge of railway track is probably too narrow, but to change the gauge would mean changing the various parts closely related to it, the rolling stock, the stations, dispatching systems, etc. Usually the more closely correlated a part of culture is with other parts the greater is its resistance to change. There is a proverb that every old tax is a good tax and every new tax is an evil. The old tax has been adjusted into the existing complex of business; the new tax may involve a complicated and painful process of readjustment. For the same reason business is impatient of "tariff tinkering," irrespective of the merits of proposed changes.

In an analogous way those who find social life satisfactory as it is are inclined to resist change. They know the rules of the road and can guide their conduct accordingly. Other rules might be inherently better but it would be necessary to live through a period of confusion before the new rules could become equally well known and usable. Persons of status and wealth tend to resist changes that may disturb their reputations, jobs or property. Social institutions seem particularly resistant to change. Thus a pagan

winter festival has persisted under the form of Christmas, taking on Christmas functions but retaining much of its original spirit. Fear of the new and respect for the traditional are change resisting attitudes, as are also the emotional attachments to national leaders, flags, religious symbols, childhood patterns. The home exerts a conservative influence resistant to social changes. If an invention succeeds at all it is by its usefulness, and being useful it is likely to make its way in time, in spite of resistances to the social changes it entails. There are conditions that often greatly facilitate the acceptance of invention and change. Thus countries with increasing incomes appear more ready to take a chance with the new. Money available for contributions and taxation offers a condition favorable to experiment. Some elements in the population are said to be addicts to change. Thus certain neurotic types, having a basic unrest, when exposed to the proper stimuli become an active element in furthering social change. So also social classes with the lowest incomes and whose chance of loss by change is least may become active agents for change, but only when points of contact with ideas of reform or revolution are made. Some psychologists claim that if children are not disciplined too early into social traditions they grow up to become active in promoting social changes that are more in accord with inherited nature than is the existing tradition. Young adults are said to favor change more than elders. A public sentiment placing a high valuation upon originality, invention, research, is conducive to social change.

Periods of great social change are usually characterized by a decline in the authority of codes of morality and by greater dependence on experiment, expediency and rationality in conduct. Similarly it is asserted that such periods are characterized by a deterioration in manners and by the frequent emergence of an uncontrolled egoism. Cultures that have undergone little social change have had time to work out by a long process of trial and error what appear to be the most suitable adjustments of the individual to the culture and the best correlations between the parts of that culture. There is thus said to be a harmonious quality in those cultures which is not found among cultures undergoing great changes. The effect of social change is to raise the questions, what is a properly integrated culture and what is the most satisfactory adjustment of culture to inherited nature? This in turn raises the question of the

values implied in progress. But whether the changes be for better or worse, the study of social changes makes the chances of control and prediction for culture as a whole appear somewhat remote. Invention has not been predicted with success and few social effects of mechanical inventions and scientific discoveries have been foreseen with certainty. With the growth of science more prediction will be possible. Indeed, for a particular area it may be quite possible to predict the introduction of culture elements from outside and the social consequences. In such cases a measure of control would even now be possible.

CHANNING, WILLIAM ELLERY (1780-1842), American clergyman. Channing became pastor of the Federal Street Church, Boston, in 1803 and remained its minister until his death. Although he is remembered today chiefly as a leader of Unitarianism he was not primarily interested in theology, and in his own time was important as a social reformer and man of letters. His aim was always religious and moral regeneration, but he proposed such practical innovations as a bakehouse for the poor, a society to advise immigrants and a fund for the ill and unemployed. An active worker in the various reform societies of Boston, he wrote on behalf of liberty of speech, temperance, prison reform, the limitation of child labor and the better treatment of apprentices. He was especially interested in the elimination of war, though he was not an absolute pacifist, and in the extension to all classes, to adults as well as children, of improved educational opportunities. During the last decade of his life he wrote several pamphlets against slavery. Underlying all his views on social problems was his faith in human perfectibility and human dignity. If this

faith led him to emphasize self-reliance and to base his hope for reform on the regeneration of the individual, it also helped to make him friendly toward the utopian dreams of his younger contemporaries. He advised and encouraged George Ripley, Theodore Parker, James F. Clarke, Horace Mann and others, and through this personal influence, as well as through his writings, he affected the social thought of the twenty years prior to the Civil War.

CHANNING, WILLIAM HENRY (1810-84), American clergyman, nephew and biographer of William Ellery Channing. He was an active worker in the movements for peace, temperance, women's suffrage and the abolition of slavery. Influenced by Fourier's writings, he called himself a socialist, but his social views were, like his uncle's, based upon religious conceptions. Despite his affiliation with the Unitarians Channing wished to disregard creeds and to make social idealism the basis of the church. To this end he organized a creedless church in New York in 1843, and in 1847 founded in Boston the Religious Union of Associationists. After 1854 most of his life was spent in England. He wrote for the *Dial* and the *Phalanx*, and edited the *Present* (1843-44) and the *Spirit of the Age* (1849-50). He was interested in and influenced the development of the North American Phalanx, Brook Farm and the Raritan Bay Union. Although he criticized Fourier as deficient in the Christian spirit of love, his writings and lectures served to disseminate Fourieristic ideas.

Consult: Frothingham, O. B., *Life of William Henry Channing* (Boston 1886).

CHAPTAL, JEAN ANTOINE (1756-1832), French chemist and economist. He was professor of chemistry at the University of Montpellier and afterwards at the École Polytechnique. In 1798 he became a member of the Institut. As minister of the interior under Bonaparte and as director general of commerce and manufactures, and later as minister, under

the restoration, he devoted himself to increasing the wealth of France. He promoted the construction of roads and canals, encouraged the bourses and chambers of commerce, founded the Société d'Encouragement pour l'Industrie Nationale and created the first trade schools in France. His fundamental preoccupation was the application of science, particularly of chemistry, to industry. He made available many new processes and materials essential to the development of the arts. His most valuable economic work, *L'industrie française*, which covers the history of economic life under the old regime and up to 1815, reveals the author as a partisan of the protectionist system although at the same time an opponent of a prohibitive tariff. His work was undoubtedly read by List, who found therein confirmation of his own views.

CHARACTER. The term character (from the Greek χαρακτήρ, a distinguishing mark) applies in common usage to the distinctive organization of traits setting off one individual from all others. In the broadest sense character is co-terminous with individuality; but in popular practical discussion the term is chiefly applied to groups of traits that have social significance and moral quality. Character used in this sense becomes the *sine qua non* of all collective adjustment and social intercourse.

Three types or aspects of character organization are of major importance in any consideration of the social function of character: first, such an integration of mental qualities that acts performed by the agent can be subsumed under a rule, if not a law (the essential quality of "the stable character" of popular language); then, singleness of purpose whereby an objective is pursued in spite of difficulties and temptations (the so-called "strong character"); and, finally, social or ethical consistency which prompts the individual to regard the consequences of his acts as affecting other people (the "good character"). The ordinary impression that "strong characters" need not necessarily be good nor "good characters" strong reveals a widespread assump-

tion of the separability of these aspects of character. Character might be defined as "an enduring psychophysical disposition to inhibit instinctive tendencies in accordance with regulative principles" (Roback, A. A., *The Psychology of Character*, New York 1928). Some other phrase, such as "prepotent impulses" or "firmly ingrained habits," may be substituted for "instinctive tendencies," but the implication remains that the more resistance there is to overcome, in order to achieve a desirable end, the more character is to be ascribed to the successfully inhibiting individual.

Although there are still metaphysicians, such as Häberlin in Switzerland and Pfänder in Germany, who invest character with a mysterious entity or force, the majority of investigators now regard it as merely an organization of psychophysical tendencies which is apt to bring forth uniform acts. Characterless persons either allow of no predictability or else violate the principle of social consistency.

There is much less agreement as to the genesis of character in the individual, the problem involving the age old issue of the relation between heredity and environment in the shaping of the mental life of the individual. Those with sociological leanings, social reformers and behaviorists, place entire emphasis on the formation of habits, on environment, imitation, suggestion or tradition (Tarde, Dewey, J. M. Baldwin, Cooley, Thomas); while the individualistically inclined, although they do not ignore the importance of education and training, are nevertheless bent on the acceptance of an inborn factor in character. How else explain, they would say, cases where the environmental conditions were just the reverse of the theoretical requirements for the formation of different characters? It is sometimes urged that this inborn factor is determined by the physical constitution and particularly by the nature of the ductless glands of an individual, while changes of character are traced to organic disturbances. Even if such observations are accepted without qualification, however, the causal relationship and its *modus operandi* in specific instances have still to be proved.

Throughout the history of the subject the social and individual aspects of character have contended for supremacy. The conspicuous position of character in every system of ethics has caused it to be identified frequently with virtue. at other times with the will and sometimes even with conscience. On the other hand, the indi-

vidualistic trend, implying a more or less inborn element, is discernible in the doctrine of the temperaments, whether envisaged under the purview of the humors (Hippocrates, Galen) or as determined by constitutional differences (Cabanis, Hallé, C. G. Carus), and may be seen again in the modern treatment of human typology (Jung, Spranger). Literary characterology, beginning with Theophrastus about 300 B.C. and continued by Hall, Overbury and Earle in England and de la Bruyère and Vauvenargues in France, combined both points of view.

The modern approach to character study was adumbrated by Francis Bacon in his *De dignitate et augmentis scientiarum*, while a program of ethology was first outlined by J. S. Mill in 1843 (*A System of Logic*). Galton in 1877 proposed an anthropological approach, taking the term to mean the totality of an individual's characteristics. The clinical phase of character study, ushered in by Bourdet in 1858, took on a more scientific aspect when De-Giovanni founded his school of clinical morphology, and through Kretschmer and his followers it has in recent years dominated the whole field of psychiatry.

The rise of pathography as developed by William Ireland and Möbius in the eighties supplied the investigator of character with new clues. At about the same time the possibilities that lay in biography were becoming apparent. But it was not until laboratory methods were adopted in the nineties by such men as Toulouse and Stern that the data gained could be relied on. Even these data, however, represented mainly knowledge of individual differences rather than of character traits in the strict sense. These explorations, combined with the statistical inquiries of Heymans and his associates in Holland, laid the basis of the psychographic method.

Toward the beginning of the twentieth century, with the development of dynamic psychology, attempts were made to place the concept of character on a more genetic foundation. Ribot and Fouillée in France, Shand and McDougall in England and Meumann in Germany attempted an analysis of character on the basis of the organization of instincts, forces (*idées-forces*), emotions, sentiments or forms of energy. Through these critical discussions the close connection between motivation and character was revealed.

Up to this time what experiments had been conducted in connection with character were of a general nature and related to bare reactions,

without regard for motives or purposes and other conative tendencies, which from the nature of the case are not subject to adequate introspection. The problem of motivation was first attacked in the laboratory by Ach in Königsberg about 1910. In the meantime the psychoanalytic school adopted an entirely different method of ascertaining why we act as we do. Speculations about the subconscious, or unconscious, the ascription of our conduct to obscure or hidden wishes and complexes, repressions and displacements, have given to the whole subject a new significance. In the Freudian system several definite character traits are linked with emotional experiences of the individual in early childhood or even in infancy, and particularly with the pregenital components of the sex instinct—oral and anal eroticism—lingering through life. More recently Freud has brought his psychology somewhat into line with traditional ethics in that he conceives of personality as constituted by an ego, which roughly corresponds to the organized perceptual workaday self, an *id*, which embraces the unorganized reservoir of instinctive impulses and cravings, and the super-ego, upon which the ego draws for its ideals and moral inspirations. The super-ego is obviously formed out of the social fiats and injunctions and is the most consolidated part of the personality.

Just before the World War two contrasted trends in the study of character began to take definite shape—the experimental and the interpretative. In 1913 G. G. Fernald brought out his questionnaire designed primarily to gain an insight into the moral concepts and behavior of delinquent and defective children. In 1914 Spranger published his *Lebensformen*, afterward expanded into a book. This essay develops the theme that there are six human types—the economic man, the theoretician, the artist, the *Machtmensch*, the social individual and the spiritually minded—each one participating in and contributing to the social organization. Character is to be estimated on the basis of what a man sees value in. The value motif thus becomes the dominant feature of character for the whole *Geisteswissenschaften* tendency (school of interpretative sciences in contra-distinction to the experimental sciences), of which Spranger is at the present time perhaps the chief spokesman.

Pari passu with this intuitive approach, the test and experimental methods initiated by Fernald were extended by Voelker in 1921 to the

point of reproducing a life situation in a restricted sphere (overstatement, cheating, etc.). Elaborations of this method were employed effectively in the following years by a number of investigators. A series of tests devised by June Downey during the same year purported to delineate symbolically an individual's will-temperament profile from various reactions to set problems or tasks, mainly in connection with writing under given conditions.

Considerable technical skill has been developed in the several experimental investigations and some interesting conclusions have emerged. One is that traits are not unitary but are conditioned by a given setting. Were such a result definitely established it would augur ill for the predictability of character, since almost every situation would have to be appraised individually. The possibility arises, however, that the various experimenters, having made their starting point not an examination of character in its integrational significance but a desultory tapping of a popularly conceived trait such as honesty, persistence, courage, suggestibility, are led astray by the popular label and forget that the name should derive its force from the sphere of activity (locus). In the last analysis it will be noted that different spheres of activity will call forth different types of response because of the specificity of the inborn tendency which is bound up with the trait. Behaviorists will, of course, ascribe the different results to different conditionings in the early stages of character formation.

Another result, less open to criticism, gained through the experimental procedure and confirming the general observation of numerous writers, is the comparatively high correlation between intelligence and character. The applications of this finding in the social sciences and particularly in education are clear.

Throughout history one aim of all educators, as of all social reformers, has been the inculcation of moral principles, the principles conceived by any group to be the basis of "character." But only in the last decade has character education been approached from a scientific angle. Since then this phase of character study has received considerable attention. Not only has a program of character education been included in many public schools but in a number of colleges the subject is now treated as a research field under the guidance of trained experimentalists. Teachers' College of Columbia University and Iowa University are at present the chief centers

of such investigations, both having been subsidized by the Institute of Social and Religious Research. The National Council on Religion in Higher Education and the Religious Education Association, as well as the American Ethical Union through its subsidiary societies, are also promoting the study of character both in its theoretical and practical aspects. It is too early to estimate the effect of such efforts on social stability or the maintenance of existing conceptions of morality, but it is not to be doubted that the relationship may be significant.

CHARCOT, JEAN MARTIN (1825-93), French neurologist. He devoted the first part of his career to pathological anatomy, but turned to clinical neurology, in which he did extremely important research at the Salpêtrière. His brilliant work in the systematic classification of nervous diseases won him great prestige, but he is known today chiefly for his study of hysteria, especially hysterio-epilepsy. In these researches he made considerable use of hypnosis, believing that susceptibility to deep hypnosis is a mark of the hysterical constitution. In opposition to the generally accepted organic neurology, he demonstrated, as had others, that ideas might cause functional nervous disorders such as paralysis, and he believed that ideas

might cure disorders of this character. In sending some patients to Lourdes he spoke of "la foi qui guérit."

His pupil, Pierre Janet, who agreed in general with Charcot's conception of hysteria, proceeded to develop the concepts of subconscious ideas and of dissociation, or splitting of personality. In 1885-86 Sigmund Freud studied under Charcot and was deeply impressed by the significance of mental factors in nervous disorders, and also by Charcot's emphasis, on one occasion, upon sexual factors in such conditions. How much of Freud's later emphasis on these points is due to Charcot's influence it is impossible to say; but certainly Charcot, Breuer and Bernheim, though representing three very different approaches, are all to be considered of major importance in leading Freud to formulate a psychological approach to hysterical personality, and thence to a new systematic psychology.

French neurology, of which Charcot was so celebrated an exponent, did much late in the nineteenth century to stimulate systematic study of suggestion and imitation in relation to such phenomena as crowd psychology and fashion.

CHARITABLE TRUSTS. In all mature systems of law devices have been developed for disposing of property for charitable purposes. The devices differ in different systems. In the Anglo-American system there are two methods of devoting property to charity. Property may be given to a charitable corporation for the objects for which it is created; or it may be given to individual trustees to hold and administer for charitable purposes.

A charitable trust differs from a private trust in two important respects. In the case of a private trust the beneficiaries are definite persons. Property held upon a charitable trust has no beneficial owner; it is devoted to the accomplishment of purposes which are or are supposed to be of benefit either to the public in general or to an undefined part of the public. In

the case of a private trust it is not possible except for a limited time to tie up property in such a way that it does not vest in a person who can dispose of it. This time is in most states limited to a period of twenty-one years after the death of designated persons living at the time of the creation of the trust. By means of a charitable trust, however, property can be taken out of commerce and perpetually devoted to designated purposes. By creating a charitable trust the owner of property can control its disposition for centuries after he is dead.

Since charitable trusts may continue indefinitely the question of obsolescence arises. If it becomes impossible or impracticable to carry out the precise purpose for which the trust was created the courts may authorize an application of the property *cy pres*. That is, the trust property may be applied to some similar charitable purpose if the general charitable intent of the creator of the trust is thereby achieved. If, however, the specific directions of the creator of the trust are an essential part of his scheme and it becomes impossible or impracticable to comply with those directions the trust will fail and the property will revert to him or to his heirs. On the whole the courts tend to be rather strict in permitting such applications and, so long as it is possible and practicable to follow them, do not authorize a departure from the directions of the creator of the trust merely because changing conditions make it unwise to follow his instructions. In order to avoid the difficulties which arise from unforeseen changes provision may be made in the trust instrument authorizing an adaptation of the trust to changing conditions; or authority may be given to devote the property to such charitable purposes as the trustees may from time to time deem wise. In some sixty cities in the United States "community trusts" have been created; the terms of these provide that the property contributed shall be devoted to such charitable purposes as may be determined from time to time by a committee of representative citizens, subject to such limitations as any donor may impose with respect to the property given by him.

From time to time restrictions have been imposed by legislation upon the creation of charitable trusts. The early mortmain acts in England provided for the forfeiture of land held by corporations unless they were licensed to hold the land. In some of the American states there are statutes restricting the amount of property which may be held by charitable corporations.

The purpose of these statutes is to prevent the taking of property out of commerce. In some states there are statutes which provide that property cannot be given by will for charitable purposes unless the will is executed at least a month or more prior to the death of the testator, and statutes which forbid a testator to leave for charitable purposes more than a certain portion, usually a third or a half, of his property, at least if he is survived by a wife or children. The purpose of these statutes is not so much to prevent accumulation of property by charitable organizations as it is to prevent testators from disinheriting their relatives in favor of a charity.

Not every benevolent purpose is recognized by law as charitable. Charitable purposes include the relief of poverty, the advancement of education, the promotion of religion and other objects which are or may reasonably be supposed to be beneficial to the public or to a part of the public. Such, for example, are the construction or maintenance of public buildings, highways and bridges, the prevention, treatment or cure of diseases, the protection of animals, the promotion of temperance.

Perhaps the oldest of charitable purposes is the relief of poverty. In England many trusts were created for this purpose long before Parliament began to afford public relief through the poor laws. The beneficiaries were often limited, however, to certain classes of needy persons and the methods of relief were various. Many of these trusts proved in course of time to do more harm than good, often causing rather than curing pauperism. The numerous trusts for the payment of doles became so pernicious that Parliament finally authorized their diversion to purposes of education.

The charitable trust has been an important instrument of religious freedom. In England it was formerly held that a trust for the promotion of religion is valid only in the case of the established religion. Gradually, however, it has come to be held that trusts to promote other religions are valid, including those of the Jews, the Roman Catholics and the various dissenting sects. It has even been held by the House of Lords that a bequest for the promotion of atheism is not illegal, though it has not been decided whether such a purpose is charitable. In the United States a trust to promote any religion is valid provided it is not one which involves illegal practices, such as polygamy. In a majority of the states in which the question has arisen it

is held that a trust for the saying of masses is charitable, although there are a few decisions to the effect that such trusts, though not illegal, are not charitable because they are primarily for the benefit of particular individuals rather than of an indefinite number of persons.

Trusts for the promotion of education have long been upheld as charitable trusts. Such trusts include trusts for the founding or support of schools and colleges, the creation of scholarships, the establishment of public libraries and museums, the endowment of public lectures, the distribution of books and pamphlets and the like. The charitable trust thus provides a method of social experimentation. Private persons can devote their property to the making of experiments which could not or would not be made with public funds. This has been particularly the case in the field of education. In privately endowed institutions it has been possible to make educational experiments which it would have been difficult if not impossible to make in public institutions. These private institutions have been enabled to conduct researches which would perhaps have imposed too heavy a drain upon the public treasury. It is also possible by means of charitable trusts to endow the teaching of doctrines and the advancement of new or unpopular causes. It makes no difference that the purpose of a trust is to present only one side of a question and that most people regard that side as the wrong side, if rational persons regard it as the right side and believe that the promotion of the purpose will benefit mankind. Institutions supported by charitable trusts can be conducted without interference from the public authorities as long as they are carrying out the purposes for which they were founded. There is always a danger, however, that a minority view will be regarded by an illiberal court as irrational and that a trust to promote it will be held invalid.

Because of the public character of charitable trusts and since there are no beneficial owners to guard against mismanagement, the responsibility for their enforcement is placed upon a public officer, the attorney general. At the suit of the attorney general the trustees may be compelled to conform to the terms of the trust. In few if any of the American states is the office of the attorney general so organized as to maintain adequate supervision over the administration of trusts. In England in the early part of the nineteenth century parliamentary commissions under the leadership of Lord Brougham spent

many years in investigating the administration of charitable trusts. Many of those investigated had been established hundreds of years before and in many cases great abuses in their administration had grown up. In 1853 a permanent Charity Commission was created by act of Parliament and was given general oversight of charitable trusts. The reports of Lord Brougham's commissions and the annual reports of the charity commissioners are a valuable source of information on charitable trusts in England and emphasize the absence of sources of information as to such trusts in the United States.

The absence of any control over the trustees except such as is exercised by the courts at the suit of the attorney general has its disadvantages as well as its merits. Although charitable trusts may be experimental in their origin they have a natural tendency to become stereotyped. This is particularly true in the case of trusts for educational or religious purposes. Opinions change, and if property is devoted forever to the teaching or preaching of opinions once held by the founder of the trust but since generally abandoned the trust may not only cease to perform a useful function but may even put a premium upon hypocrisy. The hand of the founder may preserve its grasp too long after he is dead. It is important, therefore, that the courts should exercise liberally their power to authorize departures from the terms of the trust whenever such departures become reasonable. In England the unwillingness of the courts to exercise this power except in extreme cases has necessitated the intervention of Parliament on many occasions. Since the power of legislatures in the United States is restricted by constitutional limitations it is particularly necessary that the courts should be free to authorize the adaptation of charitable trusts to changing social conditions.

CHARITY. The term charity denotes in common usage both a quality of thought or feeling and a mode of conduct with reference to those visited by misfortune. The most characteristic elements of charity are doubtless derived from the feelings and experiences associated with family life—the affection and sense of responsibility which find natural expression in the bond between parent and child and between mates. The term was first applied, however, to the extension of social obligations beyond the immediate circle of kinship. Both the sentiment and the practise of charity early acquired the sanction of religion. It became a personal virtue and a religious duty as well as a social utility. Its motivation throughout history has constantly reflected this intertwining of personal, religious and social sanctions.

Until the advent of the laissez faire philosophy the concept of charity as an individual act of mercy was of comparatively small social significance, since it was an extension of the more basic recognition of the responsibility of the group for all its members and of the communal code of ethics with respect to strangers. As long as the community represented both a religious and a political unity, the assumption of this reciprocal responsibility was a constant function. Altruism thus became an expression incidentally of a more imaginative interpretation of group self-preservation.

Ancient writings among all peoples abound in references to the twin duties of care for the aged, widowed and orphan members of the family group and help for guests, wayfarers and strangers. Among primitive peoples the succoring of wanderers and beggars assumed something of the nature of a communal rite linked with religious observances. Many centuries before the Christian era communal feasts to which strangers and unattached poor were especially invited and wayfarers' lodges and rest houses were signs of a lively sense of communal responsibility sanctioned by both religious and social considerations.

The scope of charity has undergone many changes with regard to potential beneficiaries, and the types of benefits have reflected the changing social standards of communities. The ancient Greeks, for instance, centered their attention on the relatively small number of the inhabitants known as citizens, whose leisure and means for performance of civic duties required protection in the face of economic pressure. A wide variety of experiments in public poor re-

lief, supplementing traditional private and family aid, was directed toward conserving the unity of the state by strengthening its economically weakest members. These experiments took the form of remission of taxes, annulment of debts, confiscation and redistribution of lands and surplus wealth, as well as periodical doles of cash and food. Emigration and exile were further means employed to maintain social unity within the confines of the state.

In the Roman state, as in Greece, the fact of citizenship was the basis for the right to relief. Wars of conquest, which drew men almost continually from their fields and left their families the victims of economic adversity or of the aggrandizement of stronger neighbors and which steadily displaced free labor with armies of slaves from conquered territory, filled Rome—the teeming capital of a militaristic world state—with hordes of dispossessed, dependent citizens, the plebs. The agitation of the plebs was a constant threat to social and political unity, and vast measures of public and private relief were undertaken, culminating on the one hand in the free distribution of corn by the state (*annona civica*) and on the other in private largess (*sportula*) by wealthy patricians to hordes of personal clients.

This practical group protection basis for charity was not wholly absent in the early Christian church, a persecuted sect recruited mainly from the weak and lowly members of Roman society. But the dominant elements of Christian charitable theory and practise were derived from its Jewish antecedents.

The religious aspect of Hebrew charity, like the family life in which it was nourished, had preeminently a social significance which because of the nature of the group often transcended political or territorial boundaries. It partook of the deep ethical fervor and rigid moral code of the Hebrews, especially under the spur of the prophets, who emphasized the quality of social righteousness over that of individual mercy. It was also an individual religious duty, a source of religious merit, as well as a mutual obligation for the protection of group solidarity and security. Both in the individual and social attitudes and acts the desirability of mercy was emphasized in addition to the duty of righteousness and social justice.

The Christian emphasis upon personal immortality and the importance of life after death tended to weaken charitable motives related to immediate social conditions and objectives and

to exalt motives related to the eternal personal welfare of the donor. Responsibility was transferred from the group to the individual. The cure of the souls of the sick and the unfortunate tended to take precedence over the relief of their physical or social disabilities. On the other hand, the heightened regard for the dignity and worth of every human creature as an individual personality with an immortal destiny, which the same faith expressed, gave new warmth to fraternal feeling and an immense stimulus to private charitable effort.

From the beginning Christian charity was a dynamic element in the congregational life which came to replace the political body as the center of charitable endeavor. As early as the second century church charitable funds had come into being and organized parochial charities were in process of growth. Numerous institutions for the sick, for orphans and for the aged were established. The great expansion of church charities, however, came with the accumulation of extensive endowments, administered by the monastic orders, which for a thousand years dominated the charitable thought and practises of the western world. Scores of thousands of hospitals and almshouses thus came into being, and immense resources, constantly replenished by the gifts of wealthy patrons in return for the prayers of the faithful, were dispensed to armies of beggars and vagrants, as well as to other dependents for whom special institutions were provided. An orgy of almsgiving, comparable to that which helped to demoralize Roman society but springing from religious rather than political motives, swept over the world, and only an occasional voice of protest was heard. St. Francis of Assisi (1182–1226) denounced the somewhat perfunctory and impersonal charity which had grown up under the influence of the powerful wealthy monasteries. Abandoning all his possessions, dwelling in poverty among the poor, he brought the Christian precept of charity out of the confines of the monastery into the world of men and recaptured for a time something of the individual's sense of brotherhood. Later leaders in their zeal for stimulating a life of sacrifice and service assigned specific spiritual values and rewards to specific charitable acts and thus again made the very act of almsgiving, apart from feeling or purpose, the test of religious merit.

This emphasis upon good works as a means of grace, associated with the practise of granting

indulgences in return for alms, formed one of the crucial points of attack upon the Roman Catholic church during the series of convulsions that constituted the so-called Reformation in the sixteenth century. The rise and spread of the Protestant concept of justification by faith and the denial of the reality of any abstract religious virtue to be won from particular acts dissociated from the whole moral life of the individual had much to do with the gradual replacement of the church by the state as the dominant factor in charitable effort. They not only tended to weaken the rigorous sanctions that had sustained lavish giving throughout the Middle Ages but directly contributed to the schisms that culminated in the nationalization of the church in England and other Protestant countries and to the confiscation of monasteries and other church properties there and elsewhere.

Economic and political upheavals contributed powerfully to the same end. The awakening of trade and industry following the crusades transferred the dynamic center of social life from the old feudal estates to the growing towns. There the trade and craft guilds, organized for the mutual protection of those engaged in the new economic activities, began successfully to compete with religious organizations for the loyalty of their members and gradually assumed some of the charitable functions of the church. The development of new types of social maladjustment made a place for the functioning of these non-political charitable organizations, but the town governments, with the influx of transients and unattached tradesmen and craftsmen, also participated in charitable enterprises.

The stage was thus set for the intervention of the national state as the body to administer public relief. Social disorganization, augmenting the need for charity, coincided with the decline of the old religious sanctions of private giving and the depletion of charitable resources both religious and secular. Devastating wars imposed enormous burdens of taxation; the Black Death and subsequent visitations of the plague depopulated whole towns, broke up families and set thousands adrift without means of livelihood; the enclosure of lands and their conversion from farming to sheep grazing, to meet the needs of the new wool manufacturing industry, and the ultimate dispersal of this industry from town shops to widely scattered homes in town and country added to economic confusion and dislocation.

The state at first took negative action. Futile efforts were made to restrict enclosures, to regulate wages, to prevent the movement of laborers from one place to another and to suppress begging by severe punishments. The failure of these measures led to efforts to organize and systematize begging by a license system, and this, in turn, was finally supplemented by positive attempts to control and to provide systematic relief through public agencies. Public relief therefore was at first more of an enforcement of law than a charitable act.

The first and the most comprehensive measure of this sort was the celebrated Elizabethan Poor Law of 1601, the outgrowth of many earlier experiments. In its attempt to classify dependents and to provide specific treatment suitable to the needs of each group—work for the able bodied poor, almshouse care for the infirm and apprenticeship for children—and especially in its outspoken purpose of accepting public responsibility for the care of the poor, to be discharged through public funds and by public officials, this law set a new mode of public policy. The restrictive and repressive experiments from which it grew still permeated its provisions and were intensified in later enactments as events proved its inadequacy to achieve its professed ends. Pauperism, vagrancy, beggary continued, although more and more persistently the state sought to discourage and penalize dependency.

After two hundred years new and confusing social, economic and political dislocations occasioned new efforts to deal with the problem of dependency and charitable relief. Their first manifestation was in the rise of humanitarian protests against the old repressive policy. In England the rigors and cruelties of the old poor laws and their administration were somewhat mitigated and more liberal relief measures instituted. Elsewhere, especially in France, a disposition was shown to carry to its logical conclusion the principle of state responsibility for all needy citizens and to substitute generous public aid for the mixture of public and private bounty which had survived from the old order. There was established toward the end of the eighteenth century in Hamburg, Germany, a systematic review of public relief by a central municipal authority. This was supplemented by the establishment of close and sympathetic relations between almoners and the poor in place of the perfunctory and mechanical contacts of the past.

There were, however, contrary currents. The industrial revolution, which had intensified the social disorganization and distress that had stirred the hearts of the philanthropists, brought into being a new class of capitalist manufacturers, whose interests were bound up with economy in expenditure of public funds, with the maintenance of an inexhaustible supply of cheap labor and with freedom from governmental interference in economic life, all of which were threatened by governmental philanthropic activity. Furthermore, the democratic movement of the time voiced a new political and economic philosophy of individualism, which resisted paternalistic though humanitarian measures. Faith in the right and capacity of the individual to manage his own affairs and to meet his own problems without governmental aid, buttressed by the highest economic authorities—Adam Smith and Malthus—sustained the position of the new industrialists. Amongst the reformers themselves Thomas Chalmers (1780-1847) decried public aid and emphasized the role of voluntary effort and contributions.

In the contest which ensued the working classes, supported by such philanthropists as Lord Shaftesbury, sought the protection of the law against exploitation or neglect and were opposed by industrialists and economists, who were attempting to restrain the active intervention of government in social and economic life.

As Amos Warner aptly says, "Each finally triumphed on the other's native ground." Through social legislation the rigors of the new industrial system were somewhat abated, but the poor laws were ultimately rewritten in the old restrictive spirit by the economists and capitalists. The report of the Poor Law Commission of 1834 definitely reestablished the old principles of minimum relief and the workhouse test as deterrents against unnecessary dependence upon public aid, and uniformity of administration under a central supervisory authority was sought in order to restrain undue generosity or laxity in particular poor districts.

In this whole development of public charitable activity up to the middle of the nineteenth century, as in that of the ecclesiastical charities which it largely displaced and in the communal systems of ancient Greece and Rome, is to be discerned an almost complete disregard of the effect of charity upon the individual beneficiary. Although modern charity of this early period, like that of the ancients, was motivated largely by communal purposes or class interests,

as distinguished from the personal or unworlly concerns that frequently dominated mediaeval religious charities, it disregarded, perhaps even more than the latter, its individual beneficiary's right to personality. Nor did the growing private charity of the same period, nourished by the mounting surplus wealth of the industrial middle class, differ greatly from public policy in its fundamental motivation.

The contribution to charitable theory and practise of a genuine interest in the individual beneficiary and an unqualified recognition of his rights as a person was reserved for the closing years of the nineteenth century, although it was heralded much earlier in the vigorous pleas of such leaders as John Howard, Ruskin, Carlyle and Dickens in England, Dorothy Dix in the United States and a host of others who challenged the right of society to seek its own ends at the expense of its individual members.

The movement for the recognition of the rights of personality and for the breakdown of the old concept of the poor as a class apart from the rest of the population took many forms and directions. In part it reiterated the old protest against indiscriminate almsgiving, still rampant despite the restrictive reform of the poor laws. In part it fostered a more respectful, more fraternal, less mechanical approach to the needy individual, as in the social settlement movement. In part it was rooted in the new scientific spirit cultivated in the universities from which many of its leaders were drawn, which demanded discriminating analysis and treatment of causes rather than casual treatment of symptoms.

One outstanding product of the fusion of all these dynamic elements was the charity organization movement, which sprang up in London in the late sixties and soon found its way to America and other parts of the world. Its emphasis upon the elimination of material relief and the development of the "natural resources" of persons in need doubtless dates at least as far back as Thomas Chalmers' experiments in his parish in Glasgow. Its emphasis upon organization, cooperation, non-duplication of effort, with districting and friendly visiting, was borrowed in part from the Hamburg plan of fifty years before and its more recent adaptation in the city of Elberfeld, Germany. The leaders of this movement, Charles Loch, Octavia Hill and Edward Denison, carrying on the *laissez faire* tradition of Chalmers, denounced public charity as pauperizing and demoralizing to individual initiative and as an undue enlarge-

ment of the powers of the state. But the charity organization movement made its own distinctive contribution toward a new focusing of interest in the individual beneficiary and a new respect for him; toward the elimination of personal motives and class distinctions in the practise of charity; and toward the development of scientific method and spirit in administration.

Not wholly dissociated in spirit from this movement, although of quite a different scope, was the development in America at about the same time of unpaid official bodies, often called state boards of charities and correction, with the multiple object of protecting the dependent individual against abuse, neglect or exploitation, of devising plans for his speedy restoration to normal social status and of studying the problem of dependency as a whole with the object of recommending suitable scientific preventive and curative treatment. From these state bodies there emanated soon in the United States the scientific interest, the ordered and interpreted experience and the broadened view which through the state and national conferences of charities and correction helped to introduce a new concept of charity to prepare the way for modern social work. It also supplemented private or semipublic charity by public supervision and control, thus reintroducing in somewhat modified fashion the civic elements into community life.

Probably the outstanding event of recent times in the development of charitable thought and practise was the report of the British Poor Law Commission of 1909. The majority of that commission, while recommending no drastic departure from the old administrative forms and procedures, took cognizance of the new concept of charity with its insistence upon sympathetic and disinterested administration of relief in accordance with individual needs and without violation of individual personality. The minority, frankly breaking completely away from the old tradition, demanded that charity in its old forms and connotations be definitely thrust aside; that the time honored distinctions between the poor as a class and the rest of the people be wiped out; and that in place of poor relief in the old sense specialized services through specialized public authorities be made available to all alike to meet the manifold causes and symptoms of social maladjustments.

This point of view was in some respects not so radical a departure as it seemed. Several functions formerly performed by charitable en-

deavor, such as universal provision for education and the establishment of institutions for the dependent and handicapped, were gradually being taken over as legitimate aspects of democratic public administration.

In the field of social politics those who pin their faith to the ultimate development of a democratic socialized state hail the demise of the old concept of charity. They emphasize, as part of a code of justice and in place of beneficence toward those individuals or groups whose dependent position is to a varying extent an incident of social and economic disorganization, a social responsibility in terms of services which in the past have been withheld from the poor or granted grudgingly and haltingly through private charity. In the name of orthodox economic theory others denounce charity as an interference with the free play of forces of human nature and are even more emphatic in their denunciation of any assumption of social responsibility for its members by the organized polity. From the field of the natural sciences other voices are heard, lamenting the persistence of charity or public relief as arbitrary interferences with the natural law of evolution, deploring the perpetuation of the unfit which follows as a result of protection from the necessity of achieving survival through a sifting and strengthening competition with their fellows and conflict with a hostile environment.

A realistic view of our complicated and dynamic economic and social system reveals the persistence and recurrence of maladjustments for the amelioration of which no organized provision would be made without the existence of charity. But the twentieth century concept of the scope and quality of charity is being recast in such a way as to embody more clearly a democratic philosophy of group life and a more genuine respect for individual personality.

CHARITY ORGANIZATION. See SOCIAL WORK.

CHARLEMAGNE (742-814). From his father, Pippin the Short, the last *major domus* of the Merovingian regime and the first king of the Carolingian line, Charlemagne received a twofold legacy: the Frankish kingdom embracing principally Austrasia, Neustria, Burgundy, Aquitania, Allemannia, Bavaria and Frisia—that is, modern France, Belgium, Holland and parts of Germany—and the guardianship of the western church, in whose trust reposed the remnants of Roman civilization. In its broadest aspect his career can be explained as the attempt of a man of surpassing energy and preeminent organizing ability to preserve and develop these two bequests. His conquests of Saxony, of northern Spain, of the Avars, sprang in part from the restless instinct of the born warrior and conqueror, in part from the political necessity of protecting his vast realm from the barbarians on its frontiers, in part from his assumption of a divine mission to carry Christianity into pagan lands. The same complexity of purpose led him in 774 to crown himself king of the Lombards, the potential menacers of his own authority in southern Gaul and the inveterate enemies of the papacy. For his services to the Holy See he exacted from Pope Leo III coronation as Roman Emperor at the Christmas ceremony at St. Peter's in 800. To what extent the

Holy Roman Empire was the conscious creation of Charlemagne has long been a matter of historical dispute, but no doubt can exist that it was he who made possible the actual fusion of the two component elements out of which the theory of the mediaeval empire was built. Since the culmination of the barbarian invasions the claim of the Roman Catholic church to the spiritual supremacy of the world had been tempered by the fact that the popes themselves were forced to regard the Greek Catholic rulers of Constantinople as the heirs of imperial Rome and the repositories of universal earthly authority. In Charlemagne the popes found for the first time a Roman Catholic ruler whose power enabled him to dispute the aspirations of the eastern empire and whom they could appoint joint sovereign of the western world.

Charlemagne's empire was a more or less strongly centralized state imposed upon a rudimentary but rapidly developing feudal structure. His capitularies attest that he recognized the true nature of his power. He perceived the necessity of permitting a large part of his administration to devolve upon the great lords whom Pippin as well as the last moribund Merovingians had endowed with benefices in return for political service. Satisfied if he could prevent this devolution from obstructing his own final authority he pursued the method of checking the power of the lords through the *missi dominici*, who regularly investigated the work of all public officials. Instead of seeking to arrest the development of feudal institutions he gave the whole system the appearance of emanating from him by investing the oath of vassalage with the legal sanction which it had never before received. His single reservation was that no vassal should be freed from his duties to the state. He constituted himself a quasi-suzerain over all his subjects by a capitulary issued in 802 which converted the periodic pledge of allegiance demanded from all freemen into an oath of fidelity to the king as feudal lord. The organization of the army, a matter of vital importance in Charlemagne's conquests, was feudal. When war impended a direct summons to arms was issued only to the vassals holding land immediately from Charlemagne and to the feudal lords, each of whom then organized and led to the emperor under his own command his quota of soldiers. Charlemagne's purpose in adopting such a military system was typical of his general attitude toward feudalism. The obligation of freemen to serve in the army had become an in-

creasing hardship under his regime and great numbers of them had sought escape by forfeiting their liberty and passing into the condition of serfdom. Since his army was thus depleted Charlemagne was forced to rely upon extracting from the lords the full measure of their potential resources. So long as he lived these concessions to feudalism held comparatively little hazard for the authority of the state; but they contributed to the growth of institutions already deeply rooted in the social and political fabric of the age and thus possessed the element of permanence, whereas the unity of the empire was contingent upon the mortal magic of his personal strength. In reality, the ultimate consequence of his gigantic and temporarily successful effort to create civil order was the stimulation of the forces of feudal anarchy.

Charlemagne's undoubted preeminence in his own age caused succeeding generations to inflate him into a demigod. Although after the Middle Ages the impossible legends of which he was the hero lingered only in the minds of poets, something of the same tendency to exaggerate his importance has survived until the present time. In some measure it has victimized economic and social historians, who have attributed to him the initiation of various farsighted projects to promote the economic prosperity of his realm. For the most part these assumptions are supported by meager evidence. Because he sought to extinguish the constantly smoldering embers of revolt among the Saxons by deporting them and populating their lands with peaceful tribes, it has been alleged that he carried out a methodical plan of colonizing conquered territory. On even slighter testimony it has been assumed that he systematically combined small estates and converted them into great domains for the purpose of obtaining superior yield in cultivation. As a matter of fact, the forces guiding the evolution of economic feudal institutions were beyond Charlemagne's control. The inventorial statement contained in Irminon's *Polyptyque* (ed. by Auguste Lounnon, 2 vols., Paris 1886-95) does indeed seem to indicate that the normal regime during Charlemagne's reign was that of large estate, but the emperor himself had had no hand in its introduction, nor did he make any effort to arrest the visible tendency toward the breaking up of these estates through their exploitation by numerous small tenants. Charlemagne's legislation with regard to agricultural organization and administration was really confined almost entirely to his own domains, which he jealously

guarded as his chief source of revenue and the most stable foundation of his political power. Even here his efforts to promote economy consisted chiefly of the codification of rules already in force rather than of the introduction of radical changes—a point well illustrated by the famous capitulary *De villis* (tr. in *Translations and Reprints from the Original Sources of European History* published by the University of Pennsylvania, vol. iii, no. ii). The same historians who have so greatly exaggerated Charlemagne's effect upon agricultural organization have sought to demonstrate by a superficially imposing mass of evidence that he was the center of a great industrial and commercial revival. It remains a little more than doubtful that such a revival ever took place. Certainly, from the kernels of truth which inhere in the thesis, no more daring conclusion can be drawn than that Charlemagne manifested solicitude to facilitate exchange through such measures as the attempted introduction of uniform weights and measures and the withdrawal of debased currency from circulation; and perhaps that articles in some of his capitularies tended toward the protection of certain industries.

CHARLES V (1500-58), Holy Roman emperor and (as Charles I) king of Spain. Charles was born in Ghent as duke of Burgundy and in 1519 was elected emperor. Ruler of a vast empire extending over Germany, the Netherlands, Italy, Spain and America, Charles is from a constitutional point of view a most interesting figure. All his important acts should be interpreted in terms of his efforts to bridge the gap between his mediaeval office and the modern

territorial states which composed his domains. On the one hand, he attempted to revitalize the empire and make its claim to universality effective on the foundation of his enormous territorial domains. On the other hand, he tried to reorganize Spain into a territorially and politically consolidated kingdom like that of his great rival Francis I of France and to achieve a similar consolidation of Germany.

But the ideas of the Protestant revolt rendered these several objectives mutually exclusive. It has been argued that Charles, if he had had the vision and the courage to seize upon Luther's ideas, could have made himself the protector, if not the leader, of a popularly supported reorganization of the church and the Christian faith and have shaken the power of the Roman hierarchy, which had been so fatal to previous efforts at organizing a united Europe. The authority of the imperial office, however, rested upon the universality of the Christian faith as organized in the Catholic church, and once it became apparent that the Catholic hierarchy was determined to reject the Lutheran proposals Charles was obliged to act as he did. The abandonment of the Catholic religion, moreover, would have alienated his Spanish subjects completely, and since the consolidation of Spain seemed to be easier than that of Germany this task was seized upon.

He failed to take sufficient interest in the urgently needed internal reforms for which everyone in Germany was clamoring. When he finally attempted to consolidate the German kingdom in 1547 it was too late. The new national consciousness, torn by the rival claims of a universalist dream and local allegiance to prince or city, had disintegrated. Charles' abdication and retirement in 1555-56, although partly the result of his personal desire for peace, seem to substantiate this interpretation of his reign; the constitutional ideas with which he had approached his task had proved incapable of solving the most urgent problems of his office.

CHARMONT, JOSEPH (1859-1922), French jurist. He was professor of civil law at the University of Montpellier from 1885 until his death. Charmont's outstanding contribution was his serious attempt, in spite of his affiliation with the individualistic school in jurisprudence, to harmonize the apparently conflicting views of the newer schools, particularly those of Duguit and Durkheim, with the tenets of natural law. His views find their best expression in "Le fondement de l'ordre collectif" (in *Revue de l'institut de sociologie*, vol. iii, 1921, p. 1-14), a paper written just before his death, in which he so modifies his individualistic conception of law as to make room for the claims of the sociologists, holding that individualism and socialism in law can be harmonized. He had already expressed a similar notion in his book *Le droit et l'esprit démocratique* (Montpellier 1908), devoting an entire chapter to "the socialization of law." Charmont also published *Les interprètes du code civil*, in collaboration with A. Chausse, constituting the first volume of *Livre du centenaire du code civil* (Paris 1905); *La renaissance du droit naturel* (Montpellier 1910; 2nd ed. by G. Morin, Paris 1927), the major part of which appears in *Modern French Legal Philosophy*, *Modern Legal Philosophy* series, vol. vii (New York 1916); and *Les transformations du droit civil* (Paris 1912). From 1892 to 1914 he also contributed an annual report to the *Revue de la législation et de la jurisprudence* on the state of the civil law.

CHARTERED COMPANIES. Convention has now generally narrowed the application of the term chartered company to a type of association for trade with distant points which appeared in early modern times along with the rise of strong European states and their commercial and political expansion overseas. A form of trading company sharing risks and profits had been employed by the Genoese in their highly important trade with north Africa as early as the twelfth century. Northwestern Europe was more backward in commercial organization, but toward the close of the Middle Ages the trading centers of the Low Countries and Germany had largely

adapted themselves to south European methods. Great banking firms like the Peruzzi and Bardi of Florence had maintained branches as far away as London. Even after the decline of the Flemish Hanse in the fourteenth century Low Country people played an important role in the activities of the Merchants of the Staple, monopolists in the export to the continent of the great English staples: wool, sheepskin, tin and lead. Although the Hanseatic League was not finally ejected from England until the end of the sixteenth century it had already been suffering for a long time from the aggressive competition of the English Merchants Adventurers, who dealt in various export products, especially undyed cloth, not covered by the Staplers' monopoly. These Merchants Adventurers formed a real national chartered company of the regulated type at the opening of the sixteenth century; they are mentioned here because they are often treated as the outstanding English example of a transitional type between the mediaeval guild and hanse on the one hand and the early modern joint stock concern for more distant trade and colonization on the other.

With the perfecting of ocean navigation and the rise of national states direct trade relations between distant regions began to undermine the earlier forms of commercial monopoly, which had involved several intermediaries. For example, goods from the East Indies had previously arrived in Europe by means of a number of shorter hauls, passing through many hands. Though less expensive as a whole, the direct ocean trade demanded more capital, called for more protection and involved delays longer than any which had previously been imposed upon any one set of merchants.

During the first century after the voyages of Vasco da Gama and Columbus the Italian and German trading towns lost considerably to those of Portugal and Spain, which were advantageously situated for ocean trading. Antwerp flourished for a time, largely because the Low Countries were as good a secondary distributing center for goods from Lisbon or Cadiz as they had been for those from other sources; but the final severance of the Netherlands from Spain coincided with the Spanish conquest of Portugal, and so the Dutch were shut out of the Lisbon market. After the failure of the Spanish Armada in 1588 both the Dutch and the English struck out boldly for the direct East India trade, and together with the French they also felt freer to explore the possibilities of the North

American mainland. Neither the Portuguese nor the Spanish developed strong chartered companies; this may be partially explained by the fact that both had been drawn into the conflict for commercial supremacy earlier, at a time when their economic organization was still practically mediaeval, and had thus accumulated bad precedents. Under less strict governmental supervision enterprising chartered adventurers from northern Europe out fought and out traded them.

Really adequate ships for long voyages were developed only after a long time. There was a dearth of friendly ports of call for refitting and taking on supplies. To put the trade on a sound economic basis it needed to be highly organized at both ends of the voyage, and a new spirit of business enterprise was required to discover and introduce the goods which made the most profitable cargoes in both directions. In this many sided competition the chartered company demonstrated its superiority over rigid governmental control and held a unique place in the overseas trade for nearly two centuries.

There is little but their location and their national charters to distinguish the earlier north European regulated companies from the great Italian guilds engaged in the Levant trade at an earlier period. In each case the merchant obeyed the rules laid down in the charter in order to avail himself, with his own capital, of the privileges of membership. In each group of members sometimes acted together on something like a joint stock basis. The Merchants Adventurers and the Eastland Company both overlapped the earliest national joint stock foreign trade monopolies, of which the so-called Russia, or Muscovy, Company, chartered in 1555, is perhaps the most striking example. It was the long haul, the large permanent investment and the force of strong states which gave the joint stock principle in the chartered companies a new importance and made a great difference in fact out of many obscure ones in form.

W. R. Scott suggests that the joint stock feature of the Muscovy Company, so widely copied in later charters, may have been adopted because of the familiarity of one of the founders, Sebastian Cabot, with the system in Italy. This company made huge profits from the whaling industry and some from Russian and Persian trade, but was often attacked in Parliament by people like Sir Edwin Sandys who objected on principle to joint stock enterprises. The Turkey, or Levant, Company, chartered in 1581 and em-

ploying as part of its capital the proceeds of Drake's plundering expedition around the world, abandoned the joint stock basis after about twenty years. Political attacks, Spanish privateering and high English duties on currants figure among the reasons given for adopting the regulated basis. It was at this time that some of its influential members decided to use part of the capital momentarily idle as a nucleus for the organization of the East India Company, of which the earliest minutes actually appear in a letter book of the Levant Company.

In the quite typical charter granted in 1600 to "The Governor and Company of Merchants of London trading into the East Indies" the group was given the exclusive English rights to trade in the Indian and Pacific oceans for fifteen years, with the privilege of renewal. Parliaments, ministers and kings later seized the occasions of many renewals to pare down the prerogatives contained in the charter and to exact subsidies or loans. Other English subjects could trade in those vast regions only under license from the East India Company. Land in unlimited quantities could be purchased, and on it any reasonable laws, not in conflict with those of England, could be made and enforced. Military and treaty making rights were not specifically conferred but they seem to have been assumed and were customarily exercised from the start. The company was exempt from seizure of its ships and sailors for the navy, and also from the restriction upon the export of bullion, within the limit of £30,000 in coin for each voyage. Customs duties outward were remitted for the first four voyages, and a delay in payment up to one year was allowed on later ones. Control was vested in a governor, a deputy governor and twenty-four trustees ("committees"), chosen annually by the Assembly or General Court and all under oath of allegiance to the crown.

Unlike the Dutch East India Company, founded in 1602 by the amalgamation of a number of well established smaller ventures, the English company had no permanent capital, but financed each voyage by separate subscription. Some unliquidated property was passed on at an appraised value from each voyage to the next. This arrangement was less adequate than that of the Dutch, who could set aside large sums to build forts and otherwise provide for the future—a fact which was soon to make trouble for the English company. A sum of £418,691, called the "First Joint-Stock," was subscribed in 1613 to finance the voyages of

four years. Unsatisfactory as this was, a half century elapsed before the English East India Company was able to form a single, permanent, capital stock. It paid dividends of 25 percent a year and more at times, but at others it was on the verge of transforming itself into a regulated company and even of abandoning the trade altogether.

The Dutch East India Company was from the first stronger financially and the privileges conferred by its charter, though similar, were somewhat greater. For example, it had the formal right to make treaties, plant colonies, carry on war, build forts and coin money. Any Dutchman was free to become a stockholder—a provision more liberal than the general policy of the English company. The Dutch company acted in a high handed manner in the "Spice Islands," destroying the spice industry where it could not control it, capturing the ships, destroying the posts and even massacring the garrisons of its rivals. The Dutch reached Japan in 1611 and gained exclusive trade privileges there five years later. Finally in 1653 they colonized the Cape of Good Hope, the best single position for refitting and provisioning on the route to the Indies. It has been suggested that it was the extent of the Dutch company's privileges and the lax supervision from the government at home that led to bureaucratic inefficiency in the company and finally, in the eighteenth century, to a large deficit.

A greater amount of control was thrust upon the English group largely because of the different character of the mainland trade. Certain grades of Indian cotton goods competed with English silks and woolens. The English manufacturing interests clamored for protection and secured it through a series of Calico Acts, the last in 1721 forbidding the use or sale of printed, flowered or dyed calico in England. Fourteen years later other English manufacturers who had begun to imitate Indian cotton goods obtained exemption from these prohibitions. As A. P. Usher has pointed out, English protection against East India cotton goods, after the demand for them was already strong, played an important part in bringing on the industrial revolution. A trade originally based on the demand for spices turned aside to the Asiatic mainland to get the cloth which the spice growers wanted in payment, and in the end unintentionally revolutionized textile markets and processes in Europe.

The East India business was constantly

changing as Europeans imitated the Indian goods and manufacturing competition grew up; and of course the wants of the Indies were also modified by European contacts. Government was made more difficult by these shifts in the aims of the companies, especially in a place of relatively immobile institutions like the Orient. The old colonial policies were rigid enough, with their jealousy of anything which might compete with home products, but a profit motivated business group within such a system was even further removed from a broad and statesmanlike attitude toward government. International competition, in which the companies fought over both their own pecuniary interests and the political intrigues of the mother countries, did not simplify the problem. In India especially the struggle between the French and English companies confused political issues with financial greed. Dupleix, an official of the French company in India since 1720, was made governor general in 1742. He and his half-Portuguese wife, born in India and familiar with many of the dialects, had helped the decaying Mogul empire to organize against its enemies. Native troops, trained and led by Europeans, now joined Dupleix against the English. Clive copied the scheme, however, and defeated the French; but within a century the native troop problem proved to be the undoing of the British East India Company itself, and the era of the older type of chartered monopoly was definitely brought to an end.

The economic ideas of the physiocrats and Adam Smith were rooted in the controversies over the East India trade. Early in the seventeenth century (1621) Thomas Mun demolished the cruder forms of the balance of trade arguments by showing that the transfer of precious metal eastward was offset both by the low prices of East India goods and by actual cash balances from reexports. The limits beyond which exclusion and protection hurt the real interests of British business were discovered by experience in many cases, which were to furnish ammunition for the later attacks upon the whole mercantile system.

Baltic companies, trading as they did nearer home and under more familiar conditions, were less revolutionary in organization and effects. The African companies were especially notorious for their part in the slave trade, which profoundly changed conditions both in Africa and in the parts of the Americas to which the blacks were taken. The market for European goods

could not be developed in tropical Africa as it was among the more civilized races of tropical Asia. European colonization, hardly attempted in Africa, failed in Asia but took root in tropical and subtropical America, where it was aided by the relatively sparse population and generally ineffective social organization. Of the various chartered companies in the West Indies, the French *Compagnie de Saint-Domingue*, formed in 1698, is a good example. Taking over that part of the island of Santo Domingo (Haiti) which had belonged to the short lived French Royal West India Company (1664-74) it agreed to colonize one hundred European whites and two hundred African slaves annually for fifty years. The company lasted only half that time, but founded the most important sugar colony of the eighteenth century, the trade of which was so vital to the thirteen English colonies on the mainland that it was to constitute one of the chief causes of the American Revolution.

On the American mainland and elsewhere the bewildering multiplicity of short lived French companies for trade and colonization suggests that, as earlier in the cases of Portugal and Spain, "Grand Monarchy" did not lend itself well to the prosecution of mainly economic aims. Even the English colonizing companies in the temperate zone regions of North America soon fulfilled their missions and gave way to other forms of control, either directed from the mother country or organized by the colonists themselves. The future development of these colonies was to be strongly influenced by the fact that they had been established under auspices largely economic, and that less than the usual attempt had been made to transplant the outlived political and social machinery which was hampering the transformation of Europe. Colonization presented very different problems from those of mere trade, especially as influential members of the companies settled themselves permanently in the new country.

Before the close of the seventeenth century the assault of north Europeans upon the early Portuguese and Spanish monopolies had achieved some of its aims and other aims had lost their importance. Due largely to the growth of trade and the accumulation of capital from the activities of the chartered companies, national governments had become richer, better consolidated and financially more competent. Those governments in which business men were most strongly represented forged rapidly to the front. They were able to assume tasks which

had previously been delegated to chartered companies, and these went into decline in the eighteenth century through the disappearance of the conditions under which they had made their contribution.

Chartered companies thus transformed the economic organization and wants of Europe during the sixteenth and seventeenth centuries by bringing in new goods, providing outlets for manufactures and furnishing incentives to the growth of investment capital. They also helped to colonize many temperate zone areas with Europeans and spread European influence and goods all over the world; but this very success of the companies brought them to an end. As they developed they assumed political functions which, because of their fundamentally economic aims, they were unfit to perform on any considerable scale. In the first place the rise of representative government in Europe and overseas undermined the companies. This was also a factor in the clashes of culture between the native and alien populations which later hastened the disintegration of the commercial company. The commercial company was too short sighted and inflexible in political matters; an economically developed region knows more about its own larger needs than does an alien profit seeking business group thousands of miles away.

This transformation of the world which made the old chartered companies obsolete is clearly seen in the history of late nineteenth century attempts to revive the institution. The British Royal Niger Company, chartered in 1886 under the stress of French and German competition, exercised political functions in this wild tropical region for only fourteen years before its functions were taken over by the home government and the territories administered as protectorates. The Imperial British East Africa Company of the same period was bought out and its territories converted into protectorates following a commissioner's report that five years had amply demonstrated the failure of combining trade with administration. The Belgian Congo Company of 1887 and various later concessions from the so-called Congo Free State (itself an extraordinary creation of King Leopold II out of the earlier International Association of the Congo) may be taken as a final and convincing chapter in the proof that the contemporary world condemns the granting of political functions to commercial companies. These are only scattered examples illustrating a revival of interest in the

chartered company, founded on the short lived hope that it might yield territorial or trade advantages without the responsibilities or risk to national prestige involved in more direct action.

In so far as the functions of the old chartered company are found in the present day world they are performed by other agencies. Of these the colony proper is one of the chief, as it was one of the first to supersede ventures of the earlier type when national governments became well enough integrated. A second is the protectorate, the current form of which has no very close counterpart in history. Finally, there is the ordinary business corporation operating in relatively backward countries and now generally subject to their laws, whether incorporated in the country which is the scene of its operations or in the homeland of those furnishing the capital. Citizens of one country doing business in another, incorporated or not and regardless of the existence of a concession, are now more or less protected against acts of bad faith in clear violation of the recognized code of civilized nations. This situation is perhaps the most important thing to remember in comparing present conditions with conditions when the chartered company was at the height of its power.

CHARTISM. The Chartist movement was, on the one hand, a continuation and further development of the political agitation which led to the electoral Reform Act of 1832. On the other, it was the first political struggle of the modern proletariat moving along conscious class lines. Reform had chiefly benefited the rising urban commercial middle classes. It swept away a large number of rotten boroughs, reduced the representation of others and distributed among the growing industrial sections seats thereby liberated. There was also an extension of the county franchises, which benefited the landed interest, but the household suffrage continued to be subject to a then relatively high £10 rental qualification, while a number of ancient popular franchises were abolished in the boroughs, leading to a large amount of disfranchisement.

The laboring classes were still largely outside the pale of constitutional life. Chartism was a movement carried on by these classes to obtain political power for the achievement of economic ends. Popular discontent was growing more and more intense because of the increasing use of machinery, with consequent displacement of labor, and the early harsh operation of the Poor Law of 1834. Moreover, toward the close of the decade industry and trade began again to languish, and while wages were low food was dear.

At the opening of the first Parliament of Queen Victoria's reign in 1837 an amendment to the address, moved by Mr. Thomas Wakley, a radical stalwart of the day, and seconded by Sir William Molesworth, called for an extended franchise, election by ballot and shorter parliaments. But the cabinet refused to consider further political reforms and on a division the amendment received only 20 of 529 votes. In June, 1838, several radical members of Parliament joined the leaders of the London Working Men's Association (formed in 1836) in drawing up a manifesto known as "the People's Charter." It made six political demands, most of which had long been advocated in the House of Commons by "philosophical" and other radicals: universal (i.e. manhood) suffrage, annual parliaments, vote by ballot, the abolition of the property qualification for membership in the House of Commons, payment of members and equal electoral districts. What gave the Charter

unique importance and influence was the fact that by it the political aspirations of the masses of the people were focused as never before. In addition to these political demands the Chartist movement came to stand for numerous social and economic reforms: it was on the whole anti-religious, radical in economic theory and in its views on such questions as land and tax reform.

Systematic agitation began in London and throughout the provinces and wherever the Charter was expounded organizations were formed and fighting funds raised. The movement naturally attracted most sympathy in the large industrial towns. A fervent, if eccentric and at times injudicious, leader was found in Feargus O'Connor, an Irish barrister who had once done good work for O'Connell. The leaders of the Working Men's Association—William Lovett, Henry Vincent, Henry Hetherington and others—took an active part in the crusade, being joined later by ardent idealists like Ebenezer Elliott, Ernest Jones, Thomas Cooper and the more practical James Bronterre O'Brien. O'Connor founded and edited at Leeds the *Northern Star* as a propagandist organ, and similar sheets were published in many other parts of the country.

Thomas Attwood, the Birmingham banker, proposed that a national petition be presented to Parliament and a general strike proclaimed in the event of its refusal. A national convention held in London in February, 1839, proved to be a trial of strength between the constitutional and the revolutionary groups. When the latter won the day the Birmingham contingent, largely composed of middle class politicians, withdrew. The base of operations was nevertheless removed to the Midland city for a short time and its presence there led to riots in which houses were burned. When on June 14, 1839, Attwood introduced the petition, which was said to contain a million and a quarter signatures, the House received it civilly. When on July 12 he proposed its adoption only 46 members supported the motion, with 235 against.

The first answer of the Chartist leaders to this rebuff was the proclamation of a general strike called the "sacred month." This was not carried through, but the resentment of the extremists took the form of violent demonstrations, drilling and even arming of a rude, improvised kind and an attempted rising in November at Newport. Everywhere the authorities retaliated promptly and rigorously.

For a time the movement suffered a check, but

in 1840 the National Charter Association was formed at Manchester and was soon able to boast some 400 branches with 40,000 members. The Anti-Corn Law League was then conducting its historic agitation in the same city, but attempts to organize a joint campaign came to nothing. The hard times which the laboring classes had to face early in the forties acted as fuel to flame. In August, 1842, a "sacred month" of idleness was again proclaimed and the physical force Chartists of the Manchester area, forming themselves into bands, scoured the surrounding district for a radius of fifty miles, bringing every cotton factory in Lancashire and west Yorkshire to a standstill by the simple device of extracting the boiler plugs. Many arrests were made at that time and the ring-leaders were harshly punished.

Now for a time the movement again ran slowly, although each general election saw an increase of the Charter's friends in the House of Commons. The year of revolution, 1848, witnessed both the most ambitious attempt of the movement and its final failure. Encouraged by events on the continent the Chartist leaders decided to organize an imposing national demonstration on Kennington Common, to be followed by a procession to the House of Commons, there to present a petition demanding the enactment of the "six points." The great demonstration proved a fiasco; barely one tenth of the half million people expected appeared. Although the petition was formally presented it was found that only a fraction of the six million signatures claimed for it were appended and that a large proportion were duplicated and otherwise fictitious.

The double humiliation of a foiled spectacle and a faked petition dealt a mortal blow to a movement already showing signs of exhaustion. Disappointment among the rank and file and hopes for a share in the prosperity expected to result from the victory gained in 1846 for free trade and cheap corn were other factors making steadily for a definite cleavage between the moral force and physical force wings of the party. Throughout, the leaders of Chartism had lacked the unity and concentration which had carried Cobden's league to speedy success. Some had joined the cause to win support for reforms of their own. Thus Robert Owen was at heart neither a Chartist nor a politician but a humanitarian ideologist. Attwood's enthusiasm centered on the rationalization, as he regarded it, of the currency and the amelioration of the Poor

Law. Even Feargus O'Connor, who contributed to the movement much of its motive power, divided his allegiance between the Charter and a utopian scheme embodied in the Chartist Co-operative Land Society, which was formed in 1845 for the purpose of getting people back to the land. Repeated winnowings left the active Chartists a party of the proletariat at a time when tried proletarian leadership was lacking.

In the end the movement broke up into a number of factions, the chief of them being O'Brien's Manchester Charter Association, which stood for peaceful agitation and cooperation with such middle class elements as might from time to time be sympathetic, and Ernest Jones' National Charter Association, which stood for a class war. Although the movement as a whole ran out into trade unionism, class collaboration and cooperative societies and ceased to exist as a separate political movement, it would be a mistake and an injustice to regard its adherents as misguided men who had spent their strength in vain. All their demands except that for annual parliaments were eventually enacted: the property qualification for election to the House of Commons was abolished in 1858; the principle of universal manhood suffrage was accepted by the acts of 1867, 1884 and 1918; and payment of members was enacted by the Finance Act of 1911. The importance of Chartism is also to be gauged by the facts that in the Chartist period were passed: the first real factory law (1833); the first real law for the protection of child and female mine labor (1842); a ten-hour day law (1847); and a law for the reduction of the newspaper tax (1836). Furthermore the movement looms as an important landmark in the history of class struggle; as such it had the approval and cooperation of such contemporaries as Marx and Engels and in fact was pervaded by proto-Marxian ideas. The attitude of most Chartist leaders toward Corn Law repeal, which they regarded either as a red herring dragged across the trail by the middle class to deceive the workingman or as an outright danger to working class interests, and toward antislavery agitation, which O'Brien generally characterized as a hypocritical swindle, is remarkably akin to later social-revolutionary views of liberal reformism. On the other hand the bitter tones of established church clergy, aristocrats and middle class leaders reflect the class opposition which set itself against Chartism. Although events discredited the violent tactics of the left wing, Chartism impressed British

labor with the importance of capturing the political state as a step toward economic advancement and may on the whole be looked back to as one of the headwaters of all socialistic currents in contemporary England.

CHASE, SALMON PORTLAND (1808-73), American statesman. Chase's early antislavery activities, which identified him prominently with the Liberty and Free Soil parties and won for him a reputation as defender of fugitive slaves in the Ohio courts, led to his election in 1849 as United States senator from Ohio. During his term in the Senate (1849-55) he aligned himself with the Democratic party, attempting, however, to force upon it his own antislavery views, which, while condoning the *fait accompli* of slavery in the southern states, advocated uncompromising legislation by the federal government forbidding any extension of the institution into the national domain of the territories. Unsuccessful in his attacks on the Compromise of 1850 and the Kansas-Nebraska Bill of 1854 and despairing of ending proslavery domination in the Democratic party, Chase joined the newly formed Republican party in 1855. After serving two terms as Republican governor of Ohio he was again elected senator, took his seat March 4, 1861, and resigned the next day to become secretary of the treasury in Lincoln's cabinet. In the following year he reluctantly accepted the Legal Tender Act, which established the policy—much criticized at the time and since—of making "greenbacks" legal tender for public and private debts. Chase's most notable contribution as secretary of the treasury was the establishment in 1863 of the national banking system. Despite his lack of sympathy with Lincoln, Chase continued until his resignation in July,

1864, to support the war policy of the administration. In December he was appointed chief justice of the Supreme Court and later stood with the majority of that court in the decision (February 7, 1870) invalidating the Legal Tender Act in its application to prior debts, as well as in subsequent decisions [*Mississippi v. Johnson*, 4 Wall., 71 U. S. 475 (1867); *Georgia v. Stanton*, 4 Wall., 73 U. S. 50 (1867); *Texas v. White*, 7 Wall., 74 U. S. 700 (1869); and others] which upheld the Republican policy of reconstruction.

CHASSIDISM, the term used to designate the mystical religious movement which started among the Jews of eastern Europe about the middle of the eighteenth century, is derived from the Hebrew word חסיד (pious). The followers of this movement are known as Chassidim and their opponents as Mithnagdim (protestants). While in many respects Chassidism is similar to, and almost contemporaneous with, the pietistic movements within the Protestant churches, it is in no way related to these movements and springs from a series of influences quite independent of those which were operative in western Christendom.

As an intellectual movement Chassidism is merely the culmination of a mystic strain running through the whole course of Jewish religious history and revealed in the apocalyptic portions of the Bible, in the Agadah of the Talmud and Midrash and in the Kabbala of the *Zohar* and of Isaac Luria and Chayim Vital. As such it is a protest against an overemphasized rationalism and intellectualism and an attempt to satisfy the emotional needs of a religious life. Its outburst in the eighteenth century was directed chiefly against the rule of a scholasticism that had come to dominate the whole system of Jewish education and study.

Chassidism, however, was not merely an intellectual movement. The mass character it assumed can be explained only by its intimate connection with the social and economic conditions of the time. The ravages of the decade of 1648-58, occasioned by the Cossack revolt and

the Russian and Swedish invasions of Poland, had left the great mass of the Jewish population in a wretched economic condition. They suffered on the one hand from the external oppression of their non-Jewish neighbors and on the other from the ever increasing financial burdens imposed upon them by their own *kahal* elders. Their dream of national regeneration and redemption through the messianic movements of Sabbatai Zevi and Jacob Frank ended in a fiasco. The Jewish communal organizations of the time were controlled by a self-seeking rich oligarchy and an intellectual aristocracy who for the most part existed only by flattery and cringing subservience to the rich. The unlearned mass were economically overburdened and socially despised. For a people among whom religion was the central interest in life it was natural that social discontent should take expression in a religious movement. The great masses, consisting chiefly of small innkeepers in the country and of hand workers and laborers in the villages and towns, found no comfort in the Talmudic quibbling indulged in by the rabbis nor could they follow the mystic who took flight into the fantastic realms of the Kabbala and who sought relief from the troubles of this world by completely denying them. Long before the rise of Chassidism the discontent of the masses found expression through popular orators known as *maggidim*. Its organized expression, however, came through the Chassidic movement founded by Israel Baal Shem Tov.

Israel was born about the year 1700 on the border between the provinces of Podolia and Walachia in the Ukraine. He became a "helper" in the village Talmud Torah, leading the children to and from school. He began to delve into the Kabbalistic writings and at the age of thirty-six started traveling about as a wonder healer or *baal shem*. His healing of physical ailments, however, soon became insignificant in comparison with the popularity he achieved as a healer of souls and as the teacher of a new doctrine. To distinguish him from other wonder healers he was called Baal Shem Tov (the *good* master of the Name) or, in abbreviated form, the Besht.

The Besht settled in Medzhibozh in 1740 and for the remainder of his life this was the center for the large following attracted to his teaching. His work after his death was carried on chiefly by two of his disciples, Jacob Joseph Hakohen and Baer of Mezherich, also known as the Maggid of Mezherich. The former gave Chassidism its first literary work, the *Toledoth Jakob*

Joseph (Korez 1780), which was both a severe indictment of the Talmudists and a faithful exposition of the teachings of the Besht. Baer was the organizing genius of the movement. He gathered around him a group of distinguished Talmudists who had become converted to the new movement and then sent them out as missionaries throughout the various Jewish communities of Poland, the Ukraine and White Russia to preach the new doctrine and organize themselves against the attacks of the Mithnagdim. By this time the Talmudists had awakened to the dangers of the new movement and combated the Chassidim as the followers of a heretical sect. Strengthened by the support of the greatest Talmudist of the time, Elijah Gaon of Vilna (1720-97), they published bans of excommunication against the Chassidim calling for their complete social and religious ostracism. The struggle became so acute that the Russian government intervened and upon information supplied by the Mithnagdim twice arrested the leader of the Lithuanian Chassidim, Shneur Zalman, on charges of political disloyalty, in 1798 and 1800. He was freed only after the authorities were fully convinced of the non-political character of the movement. Chassidism, however, never definitely assumed the character of a sect, as did, for instance, Karaism. While many differences continued to separate them from their opponents they remained and carried on their activity as an integral part of the Jewish population. With the break up of the Pale after the World War many Chassidic rabbis emigrated to the United States and were received by their Chassidim who had preceded them to this country. Because of the complete secularization of Jewish life and the chaotic condition of Jewish religious institutions in the United States, however, they have failed to become the powerful factor they once were, and to a limited extent still are, in eastern Europe.

The Besht, himself a man of the people, realized that the religious needs of the masses were not met by the leaders of the day. In place of the rabbinic stress on learning as the test of true piety he emphasized prayer and the practise of the moral virtues; in place of the emphasis on the performance of the commands of the law he insisted on the greater importance of the *kavanna*, or moral will and purpose behind the performance of these duties; in place of the current air of haughty arrogance assumed by the learned classes he practised and preached a doctrine of humility that aimed to bridge the

wide gulf between the various social strata. Finally, in contrast to the ascetic mode of living idealized by the older Kabbalists he taught a religion that abounded in ecstasy and in the joy of life. Through his pantheism and his doctrine of the interaction of the upper and lower worlds he brought the material as well as the spiritual world within the realm of the divine. God must be worshiped in all ways and through every act of daily life. Thus Chassidism was a doctrine based on simple emotions and simple virtues and as such had a particular appeal to the poorer classes. They too now found themselves considered an important element in the community and deserving of a share in this world as well as that of the kingdom to come. Chassidism proved a cohesive bond that united the disjointed elements of the lower classes, filled them with a greater degree of self-esteem and thus introduced a new creative element into Jewish life.

The Besht, moreover, as well as many Chassidic rabbis of the later period, actively participated in alleviating the intolerable condition of the masses. Realizing that "poverty only served to distract the thoughts of man from his Creator" they took the lead in the organization and collection of funds for the establishment of charitable institutions and very often utilized the authority and respect they acquired even among the non-Jewish population to intercede before landowners on behalf of tax burdened or dispossessed Jewish tenants.

With the passing of the generation of the Maggid and his disciples the period of degeneration and eventual stagnation of the Chassidic movement set in. Although it continued to spread until it gathered over half the Jews of eastern Europe under its standard it never reached either in spontaneity or in caliber of its leadership the glories of its earlier days. Chiefly responsible for this was the central position assumed by Tzaddikism. The *tzaddik*, or *rebbe*, as the spiritual leader of the Chassidim was called, was a sort of intermediary between God and His people on earth. Through his prayers and intercession the *tzaddik* supposedly was able to influence the divine will and thus work miracles. The whole life of the Chassid centered in the person of his *tzaddik*. He came to him for help or advice on matters of health, family relations, business or any other matters. In order to insure to the *tzaddik* perfect tranquility and freedom from material care the Chassidim contributed to his support and often devoted their last pennies to this purpose. In time the position

of *tzaddik* assumed a dynastic character. The descendants of the earlier leaders settled in various Jewish communities and their title and the moral authority that went with it became hereditary. Often the fiercest rivalry developed between one dynasty and another. The home of the *tzaddik*, frequently a palatial mansion, was known as the "court" of the *tzaddik*. From the court he directed the affairs of his followers scattered for many miles around. In regions where the Jews were enfranchised the *tzaddik* was, and still is, a very important factor in the political life of the country, able to sway the votes of his followers at will.

This implicit faith in the *tzaddik*, the Chassidic overoptimism as to the eventual outcome of all troubles and the practise of long attendance at the court of the *tzaddik* tended to produce a fatalistic resignation, mental laziness and social laxity. Out of the importance which Tzaddikism attached to joy and the need for stimulating it artificially when necessary came a proclivity toward alcoholism, and with the belief in the wonder working powers of the *tzaddik* came a general superstitious attitude that later proved the foe of enlightenment and change.

Chassidism has, however, left a lasting imprint on Jewish life by its elevation of the common man, its break up of rigid class distinctions and the raising of the social status of women. By its accentuation of emotionalism, its direction of Jewish interest inward and above all by the central place assumed by Palestine in Chassidic life and literature it became one of the most powerful stimuli toward the development of the Jewish national movement. With its unusual development and accumulation of folk songs, folk tales, legends and parables it proved one of the sources of a national art and literature. Viewed from a rationalistic westernized standpoint Chassidism has been branded as an obscurantist, fanatical and superstitious movement that retarded the penetration of the benefits of western culture for another century. Approached, however, with a sympathetic appreciation of the life and history of east European Jewry it appears as a movement sprung from an inner necessity, deeply rooted in the stream of Jewish religious experience and as such the most far reaching and vital religious movement of the modern Jewish period.

CHASTITY. In primitive societies there are several factors leading to the injunction of chastity. The biological factor, the repulsion of the male by females during pregnancy and lactation, found among all animals, obtains in the form of tabus among the majority of uncultured races. Menstruation, commonly ascribed to the dreaded influence of the moon, likewise gives rise to a strict and universal tabu. To this class may also be referred the custom of exogamy and the prohibition of incest, favored by the male's wandering and the female's sedentary disposition and perhaps connected with the protection of very young females (younger sisters) in communities where mothers and elder sisters are regarded with awe by the younger males.

Chastity tabus arise also from proprietary claims. In most uncultured races women's sexual freedom is limited only by marital claims to fidelity, often laxly enforced and qualified by those of tribal brotherhood, hospitality and ritual license. Prenuptial chastity is not enjoined. The retrospective claim appears to be connected with infant betrothal, particularly in the brides of sacred chiefs. Feminine chastity, lax throughout the lower cultures, is stringently enforced where the men possess considerable purchasing power, as in pastoral societies. In these and in the higher cultures developed out of them adultery is often punished with great severity and proof of the bride's virginity is demanded.

Chastity is often enjoined also on religious grounds. The magico-religious value assigned to sexual abstinence originally belongs to the same order as that ascribed to observances, typically represented by rites of mourning, which are intended to avert the envy of supernatural beings. The Greek word *αγγελία* (chastity), originally denoting abstention from food as well as from sexual activity, had specific reference to rites of mourning and "aversion." While many prim-

itive rites intended to stimulate generative powers entail sexual license, others relating to operations deemed dangerous, such as war, hunting, fishing, the preparation of food, the offering of sacrifices, priestly functions of intercession, are thought to demand abstention from indulgence that might excite envy. To this motive is added, in the case of warriors, hunters and fishers, a desire to protect themselves against feminine influences deemed detrimental to masculine pursuits. The hygienic advantages of chastity seldom appear to be considered. In oriental cultures asceticism was held to confer magical powers irrespectively of the practitioner's moral depravity.

In higher pastoral and oriental cultures the emphasis laid on chastity had reference chiefly to feminine continence. Rigorous ideals of that virtue are found without a suggestion of its applicability to men. Among the Greeks the conception of chastity, apart from uxorial obligations and ritual requirements, existed only as part of the ideal of moderation, applicable equally to eating and drinking. Among the Romans marital claims were thought to imply reciprocity and example.

Post-exilic Judaism was characterized by obliteration of the distinction between ritual and moral injunctions and by the extension of functional priestly obligations to all members of the religious state. Ritual continence thence came to be regarded as a virtue of general applicability, and ritual unfitness, or impurity, as sin. That tendency, counteracted by the Jewish ideal of procreancy, became emphasized among the primitive Christian sects, with whom renunciation was no longer the means of magic power but the condition of salvation. Early Christianity carried that conception to its extreme limit. In an emotional, religious atmosphere continence, owing to the power of the instinctive forces which it had to combat, became the center of moral preoccupation and sex the essence of sin. Marriage appeared to many an unworthy compromise. No writer in the early Christian centuries fails to affirm the superiority of virginity, a view confirmed by the Council of Trent. The consequences of stamping out sexual activity were accounted preferable to the propagation of mankind by sin.

Although sexual prohibitions date from the infancy of humanity chastity nowhere appears to have assumed the character of a substantive moral virtue until the development, under special conditions, of Christian ethics. From these

the moral tradition of western civilization is derived. The misapprehension which regards that tradition as the term of an evolution continuous from primitive stages contains a sufficient measure of truth to render it misleading and impairs the value of many discussions.

During the Middle Ages the influence of Christian morality was brought to bear on barbarian peoples whose conceptions corresponded to their cultural phase. Resulting compromises were on the whole characterized by evasion in practise of principles formally professed. The ruling classes seldom gave up their immemorial habits. The license was veiled, however, by an idealization which had the notable effect of developing romantic and sentimental conceptions. Christian morality was more solidly realized among the burgher classes and received a fresh impetus with their rise to power and the growth of Puritanism, which stressed their moral superiority over the nobles.

The present period shows signs of a revolt against the moral tradition and a disposition to reconsider the foundations of the ideal of chastity. Physiological science seems to indicate that complete sexual abstinence and even excessive repression are fraught with dangers scarcely less grave than sexual excess. As with other physiological functions the optimum consists in moderate activity. But sexual activity is always psychophysiological. It not only bears on the sexual instinct in the narrow sense but also on the instincts which are at the root of social affections. These and the biological sexual instinct are in many respects antagonistic. Unrestricted license is psychologically, no less than socially, incompatible with those instincts which constitute the psychical bond of the relation between men and women. Those bonds cannot be preserved without subjecting sexual activity to limitations dictated by mutual devotion and common interests.

CHATEAUBRIAND, FRANÇOIS AUGUSTE RENÉ, VICOMTE DE (1768-1848), French man of letters, diplomat and politician. His political writings include the *Essai historique, politique et moral sur les révolutions* (1797), the *Études historiques* (1831) and much newspaper writing and pamphleteering. His imaginative works, like the *Génie du christianisme* (1802), are also affected by his attitude toward politics and especially toward the French Revolution. There are political implications even in his characteristic romantic attitude as displayed in his novels. His exaltation of the romantic hero, misunderstood and suffering, at war with a world which refuses to measure up to his desires, is an anarchistic reading of Rousseau. Chateaubriand often despairs of everything; the legitimist is strangely doubled with the nihilist.

The *Essai . . . sur les révolutions*, written in England, where Chateaubriand was living as an émigré, is the pessimistic and somewhat confused work of a young man still influenced by the philosophy of the eighteenth century salon, and was subsequently disavowed by its author. Chateaubriand sets out to discredit the revolution by proving its futility and examines with great parade of learning twelve significant revolutions of history. He finds that they all follow courses essentially the same, and he arrives at the skeptical conclusion that, in spite of momentary benefits which it may confer, the revolutionary cycle must inevitably return to its starting point. Borrowing from the *philosophes* he repudiates Christianity, but at the same time rejects the hope of man's perfectibility through his own efforts. Chateaubriand's conversion to Roman Catholicism about 1799 made him in reality a much less complete adversary of the revolution. With a suddenly released poetic imagination and romantic fervor, which were to affect French literature and thought throughout the nineteenth century, he records in the *Génie du christianisme* his ecstasy at finding in Christianity a powerful artistic inspiration as well as evidence of the idea of progress and of

a gradual improvement in the human race. "Its steady circle widens itself with the growth of knowledge and liberty, while the Cross marks forever its fixed center." The appearance of these volumes on April 14, 1802, four days before Napoleon's announcement of the final signing of the Concordat, established the fame of the author, although it laid his work open to criticism as an "ouvrage de circonstance." The favor of the emperor was discontinued in 1807 as the result of an article written by Chateaubriand for the *Mercur* in which he attacked Napoleon's absolutism.

With the return of the Bourbons Chateaubriand ended his retirement and entered practical politics, championing in his pamphlet *De la monarchie selon la charte* (1816) a constitutional monarchy. He was still a believer in legitimacy, but a legitimacy taught by exile that its subjects have legitimate individual rights and liberties. During his political and diplomatic career under the Restoration he was in the main an advocate of liberal measures, keenly aware of the extent to which the social changes resulting from the new industrial era were undermining the supports of monarchy. Chateaubriand's faith in the Catholic church remained unshaken. In his *Études historiques* he presents his most explicit statement of the significant role which it has played in human progress. Denying on the one hand the thesis of Voltaire's *Essai . . . sur les mœurs* and on the other that of Bossuet's *Discours sur l'histoire universelle*, Chateaubriand conceives of mankind as participating actively, under divine guidance, in the working out of its own destiny.

CHATHAM, EARL OF. *See* PITT, WILLIAM.

CHAUTAUQUA is the designation for a religious, moral, social and educational movement taking its name from Chautauqua, New York, its point of origin. It grew out of an annual summer camp meeting which had been held for a number of years at Chautauqua under the auspices of the Methodist Episcopal church. In 1873 Rev. J. H. Vincent, who later became bishop, and Lewis Miller, a wealthy business man of Akron, Ohio, proposed that the camp meeting should specialize in the discussion of problems relating to Sunday School management and method. In 1874 the Sunday School 'Teachers' Assembly was organized; its success was marked and other evangelical denominations soon began to participate. As a result of this growth in attendance the programs became correspondingly enlarged and diversified. With the addition of lectures and formal courses on Sunday School methods, Biblical history, Biblical geography, Hebrew, Greek, sacred music, etc., the camp meeting developed into a full fledged summer school for religious education. During twenty-five years it continued to introduce new courses of study until the total number exceeded two hundred and the length of the session had been extended from twelve to fifty days. Permanent classroom buildings were erected as well as auditoriums, hotels, cottages, etc., to accommodate those who came to this watering place for rest and recreation in a wholesome moral environment. For visitors who did not care for formal study a program of popular and inspirational lectures supplemented with good music and wholesome entertainment was supplied. The daily programs included lectures by noted men and women in the fields of education, politics, religion, industry, literature, music and science. These latter features soon became the popular conception of Chautauqua, attracting people in larger numbers from neighboring states. During a single season as many as 150,000 are reported to have been in residence for periods of varying length, exclusive of those coming for a single day. The institution, which now may be considered to be on a permanent basis, is financed primarily by the daily and seasonal gate receipts plus the profits accruing from the hotels, stores and other concessions on the ground.

Within a dozen years following the organization of the first assembly at Chautauqua Lake no less than fifty independent summer camp meetings calling themselves Chautauquas were scattered from coast to coast. Although many lasted only for a short while, some have become

almost as famous as the mother institution. Among the most successful are those at Winona Lake, Indiana; Lakeside, Ohio; Boulder, Colorado; Bay View, Michigan; Franklin, Ohio; and Ocean Grove, New Jersey. While no two of these are alike in detail, they share the general function of combining recreation with entertainment, inspiration and education of a popular brand. In some, such as Winona Lake and Ocean Grove, the summer program consists largely of an almost continuous succession of religious conventions, while others stress educational, inspirational or musical features.

A second and more familiar form at the present time is the traveling Chautauqua, initiated in 1904 as a commercial venture and built upon the circuit plan. During the summer months three to seven-day programs are given in circus tents for towns of from 500 to 10,000 population. The "talent," i.e. lecturers, musicians and other performers, moves from town to town in the circuit. Because of relatively short distances between stands and long term contracts which could be made with the "talent" the plan proved economically successful and numerous traveling Chautauquas were established. The usual daily program consists of a lecture together with musical, dramatic or other entertainment at both afternoon and evening sessions. A central theme, such as community improvement, public health, international relations, civic pride, education, usually dominates the program.

This type of Chautauqua rapidly grew in public favor. In 1912 there were in six midwestern states alone almost 600 such Chautauquas. The movement reached its height in 1921, at which time approximately 12,000 American and Canadian communities were thus served. It has been estimated that approximately 5,000,000 people were reached. Since 1921 there has been a steady decline in the number of communities sponsoring these gatherings. Small Chautauquas have tended to disappear, much of the business being concentrated in the hands of three large traveling organizations, the Redpath, Swarthmore and Community Chautauquas. In 1930 it is estimated that there is less than 10 percent as many towns with an annual Chautauqua as there was in 1921. Approximately 75 percent of these towns have less than 1500 population, being mostly inland rural centers. Among the reasons for this decrease is the competition of the automobile, the cinema and the radio.

The early practise of presenting lecturers who dealt with controversial topics has gradually

been supplanted. In recent years community leaders, on whom the Chautauqua management leans for support, have even intervened to prevent the appearance of a lecturer who they feared might express views antagonistic to their economic interests. As a result inspirational lecturing has been more and more substituted. Since the war the Chautauquas have tended to provide a type of Broadway drama and jazz music which in an earlier period would have met the severe moral reproach of the rural consumer. There has been a marked tendency to give the public what it presumably desires as long as such a policy proves profitable. The recent decline in business has as yet brought no marked improvement in the quality of the product. Despite the fact that this has not been the best which might have been offered, it has been superior to other entertainment available in rural communities.

Several by-products have sprung from the Chautauqua movement, each with its own social value. One is the summer school movement, now participated in by most resident colleges and universities and largely modeled after the successful experiment at Chautauqua. The Chautauqua summer school was also one of the two sources of the modern correspondence school. Dr. William Rainey Harper, a young professor in this school, demonstrated the practicability of this method of instruction in order to continue the educational work begun in the summer. A third by-product was the Chautauqua Literary and Scientific Circle, founded in 1878 and constituting a network of local affiliated groups throughout the United States, which undertook under the guidance of Chautauqua teachers a definite program of reading and study of a general cultural nature with the Bible as a basis. This development has been copied in various foreign countries and has proved particularly successful in England.

CHAUVINISM is the excited demand for the limitless and violent expansion of the state. The term came into circulation in France where it referred to a much wounded follower of Napoleon, whose idolatrous admiration for the emperor served as the prototype of all blind enthusiasm for national military glory. In England more frequent use has been made of the term "jingoism" which, derived probably from the "by jingo!" of a popular song, came into currency in 1877 in a wave of frenzy against Russia. The phenomenon common to both terms was sufficiently manifest in early political systems, but it has become peculiarly conspicuous in the conflicts among modern nation states, where huge populations are sentimentally bound to the fortunes of their political unit. In this context it is an inflammable blend of patriotism, nationalism, imperialism and militarism and reaches its height during the critical days of an international crisis.

Since chauvinism is a crowd phenomenon in the technical sense of the term it belongs to the sphere of collective behavior where reflection is at a minimum and where the emotional processes are rampant. Indeed, political life in general derives its vitality from the displacement of private motives upon public symbols, and this process is particularly prominent in the war crisis. When the community is confronted by threats and provocations there is a concurrent regression among the individual members toward powerful primitive impulses. Chauvinistic boasts, threats, exhortations and adulations are part of the process by which the aroused impulses of the community become concentrated around and displaced upon the symbol of the state and the courses of action presumed to be essential. The heightened tension level of the community is thus given some measure of coherent organization. Chauvinism extends the individual self to a national field of action and facilitates the mobilization of the community for instant attack and defense.

The particular motives which interplay in chauvinism are exposed especially in the course of the intensive scrutiny of the individual by psychopathological methods. Hate, love, self-punishment and a host of nuanced motives are brought into action. Chauvinistic sentiment abounds in the use of intangible symbols like "national honor," and every channel of communication adds to the reverberation produced by every demonstration of excitement. The heightening of the tension continues until, in

the overt instance, there occurs that plunge into action which is followed by the "peacefulness of being at war."

CHAVCHAVADZE, ILIA (1837-1907), Georgian publicist and poet. In 1863 he founded the *Sakartvelos Moambe* (Narrator of Georgia), which represented the populist-realistic school in literature and western liberalism in politics. Later he established and edited the newspaper *Iveria* (1877) in which for thirty years he discussed in a humane and liberal spirit the current social and political problems of Georgia.

At the outset of his public career Chavchavadze associated himself with the movement for the abolition of serfdom. In the press and in separately printed novels and poems he pointed to the danger of the widening gulf between the landowning nobility and the peasant serfs, deplored the deadening influence of serfdom. With the emancipation of the peasants he became a judicial mediator between peasants and landowners (1864-68) and later judge of one of the lower courts (1868-74). At this time he advocated reestablishment of the "broken bridge," that is, the collaboration of the classes. From the Russian government he demanded the introduction of local self-government (*zemstvo*) adapted to the customs and usages of Georgia.

Chavchavadze is no less important as a literary figure and folklorist. He carried on a successful struggle against the conventional themes, style and vocabulary of the romantic period. Most of his novels and poems dealt realistically with social problems and were written in a language close to the living Georgian tongue. In his periodical publications he printed many local ballads, songs and customs found and transcribed by him and his followers. The champion of a political and cultural national renaissance and of liberal agrarian reforms, Chavchavadze came to be regarded as the "prophet" of his people.

CHAYKOVSKY, NIKOLAY VASSILIE-VICH (1850-1926), Russian populist socialist. As a student in the University of St. Petersburg he helped to organize an informal association of young people, "the Chaykovsky circle," which subsequently played an important part in the revolutionary movement. Its members were humanitarian socialists and at first confined their activity to peaceful propaganda. When under pressure of government persecution the association became increasingly violent in its methods, Chaykovsky parted from his former friends and joined Malikov, who preached the religion of "God in man," true regeneration through the development of man's godlike traits. In 1875 Chaykovsky led a group of followers in the establishment of an agricultural communistic settlement in Kansas. The experiment lasted only two years. Chaykovsky returned to Europe and in 1880 settled in London, where he acquired a considerable reputation in English and Russian circles. He renewed his interest in the revolutionary movement, helped to win for it the sympathy of foreign public opinion, collected funds for the relief of political prisoners and assisted in the work of an organization which published a non-party revolutionary newspaper distributed in Russia. For a time Chaykovsky shared the views of the anarchist Kropotkin but later he became a member of the London group of the Russian Socialist Revolutionary party.

In 1907 Chaykovsky reentered Russia under an assumed name, was arrested and tried on a charge of revolutionary conspiracy, but was acquitted for lack of evidence. He remained in Russia and devoted his entire energy to the co-operative movement. A few years before the outbreak of the 1917 revolution he took a hand in politics and became prominently associated with the Laborite group and later the Laborite People's Socialist party. With the advent of the Bolsheviks he joined the anti-Soviet group, the Union for the Regeneration of Russia, and in the autumn of 1918 went to Archangelsk to lend the prestige of his name to the counter-Bolshevik movement in the north. He became the head of the provisional government of the northern region, and in 1919 went to Paris to solicit more active aid from the Entente powers. In 1920, still convinced of the possibility of saving the White forces in the south, he went to Ekaterinodar, offering his assistance to General Denikin in the reorganization of his government. Chaykovsky died in Paris, a few months after

his seventy-fifth birthday had been publicly celebrated.

CHECK. The check (English usage, cheque) comes within the general class of bills of exchange and is defined by the Negotiable Instruments Law as a "bill of exchange drawn on a bank payable on demand." According to the definition as expanded through legal interpretation a check is an unconditional order in writing addressed by a person (the drawer) to a bank, signed by the drawer, requiring the bank to which it is addressed to pay a sum certain in money on demand to a person named or to his order or to bearer.

The check is distinguished from other bills of exchange primarily in that it is drawn on a bank and purportedly against a deposit. It does not serve as an assignment of the deposit, however, and the bank's unqualified liability for immediate payment in legal tender money is to the drawer, not to the holder. Some of the states of the United States have provided that banks may pay checks by means of drafts or reserve deposits unless the drawer specifies otherwise. Only certification, a distinctively American procedure not widely used now, can transfer the bank's contract from the depositor to the holder of the check. Legally, however, the check is an implied promise to pay on the part of the drawer and the bank is required to honor it if properly drawn and presented and if covered by a deposit. Upon this attribute and upon its consequent ability to replace paper money, over which it has the advantage of greater safety, convenience and accounting utility, the rapid development of the use of "deposit currency" in modern times is based.

Although checks were probably used in Palermo, Italy, as early as 1416 A.D. and in England in the latter part of the seventeenth century their elevation to first rank as a medium of exchange in commercially advanced nations came in the course of the nineteenth century. The development proceeded irregularly in different countries as a result of differences in banking facilities and service, density of population, general education and intelligence of the people and the attitude of the government as evidenced in its fiscal policy and legal code. Confidence in its safety and certainty, essential to the spread of the use of the check, has been

increased by devices such as limited or "zur Verrechnung" endorsement or crossing, which, however, restrict negotiability, and by special penal codes aimed at preventing check frauds. Stamp taxes in general retard the development, although England, which with the United States is the leader in the use of checks, maintains such a tax. It is estimated that checks effect probably 90 percent of the transactions in these two countries. They are also important factors in Canada and Germany. In the last named country, however, as in Holland and Switzerland, the function of the check is partially performed by a well organized *Giro* system under which sums of money are transferred from account to account by non-negotiable orders. In France, despite governmental encouragement, the check remains of minor, if increasing, importance. In nearly all other countries its use is negligible.

CHECKS AND BALANCES. The advantage of "checks and balances" between different organs of government was first emphasized in the theory of so-called "mixed government" elaborated by Polybius (*Histories* vi, 3-10) and revived by Machiavelli (*Discorsi . . . sopra la prima decade de Tito Livio*). According to this theory a government of any of the "pure" types—monarchy, aristocracy or democracy—must inevitably degenerate into the perverted form of that type: monarchy into despotism, aristocracy into oligarchy, democracy into mob rule. To avoid such perversion the government must at the outset be given a "mixed" form, that is, it must include organs belonging to each of the simple types. The aristocratic and democratic organs will then check the degeneration of the monarchical organ, the monarchical and democratic organs will prevent the aristocratic organ from becoming oligarchic and the aristocratic and monarchical organs will supply a guaranty against mob rule. In this form the theory was

essentially one of balance between the two principal social classes, with a monarchical element to mediate between them. It was accepted in essentials by Calvin (*Institutes of the Christian Religion*, bk. iv, ch. xx, par. 8) and inherited by the leaders of early Massachusetts. In the eighteenth century it was revived and elaborated by John Adams.

During the religious wars in France and the contest between crown and Parliament in seventeenth century England new use was found for a doctrine of checks and balances. The political philosophy of the Middle Ages held that the king was bound by "fundamental" law. It had been pointed out by Buchanan that if the king was free, as the absolutists contended, to make his own interpretations of this law it could supply no effective limitation on his power. It was therefore argued that a special organ of government was necessary to enforce fundamental law against the king or to share with him the power of interpreting it. Such an organ was seen by Calvin, Buchanan and the French *Ligueur* writers in the representative assemblies, or estates of the realm. Royal power so limited came in England to be called "mixed monarchy," of which the essential feature was that the power of the crown was checked and balanced by Parliament. This view culminated in the theory of Locke. Locke's starting point is still the opposition between a king, claiming to be absolute, and the representatives of the people, but in his generalized statement of the problem the opposition comes to be one between legislative and executive powers. This notion of a balance between different departments of government rather than between particular historical institutions or social classes was elaborated by Montesquieu, from whom it passed to the framers of the American constitutions. Montesquieu's concern was to discover an organization of government which would be most favorable to the security of the individual. This he thought could best be attained under a constitutional system which subdivided and distributed governmental powers among a number of different organs so checked and balanced against one another that an attempt by any one of them against individual rights would fail through want of the necessary cooperation by the others.

The popularity in the American colonies of the doctrine of checks and balances resulted in part from colonial experience. The advantage which accrued to colonial legislatures from their

power of withholding the salary of royal governors illustrated the value of a legislative check on the executive. At the close of the Revolutionary War the distrust of legislative power engendered by radical legislation led to a desire for both an executive and a judicial check on the legislature. The philosophy of checks and balances is stated by Madison in *The Federalist*. His argument is that, power being "of an encroaching nature," different organs of government can be kept within their constitutional limits only if checks against them are placed in the hands of rival organs. To the argument that such an arrangement violates the principle of separation of powers Madison answered that that principle requires no more than that the whole power of one department of government must not be "exercised by the same hands which possess the whole power of another department."

In the federal constitution John Adams was able to detect eight different sets of checks and balances (letter to John Taylor in *The Works of John Adams*, vol. vi, p. 467-68). Some of these have proved ineffective. Only those have been operative which provide that neither of two governmental organs deriving from independent sources can complete a legally valid result without the concurrence of the other. The possibility of a deadlock in such instances has often been realized, most frequently perhaps in the relations between the president and Senate concerning treaties and appointments. Deadlocks have also occasionally arisen between the two houses and between the president and Congress in matters of legislation.

The system of checks and balances has been adopted in American state and local, as well as national, government, and the philosophy underlying it has become part of the political creed accepted without question by most Americans. Recent American students of political science have, however, questioned whether government by checks and balances leaves final power in the hands of the people. It has been pointed out that "the actual operation of these checks and balances . . . has resulted in irritation and bickering between the departments. . . . The executive is the most conspicuous single official. He is elected upon a platform of pledges for legislation. He seeks to redeem those pledges by promoting the introduction of bills and pushing them through the legislature. The legislature feels hostile toward the executive for attempting to coerce its action. The executive loses patience with the legislature for not redeeming the pledges

of the executive to the electorate. . . . The result is that each of the departments of government fails to work in harmony with the others. Each tends to retire to its own constitutional sphere and there spend considerable time in doing what it pleases, regardless of the other departments, and from time to time blocking and hampering them. In this way the least progress is made with the important business of legislation and the functioning of the executive and the judicial departments" (Kales, p. 10-12). At the same time "in consequence of the division of political power into so many small fragments, the ordinary citizen does not take interest enough in any one of them, and leaves the control of public affairs too exclusively in the hands of the professional politicians" (Lowell, p. 58).

The theory of checks and balances proceeds on the assumption inherited from a period of absolute government that the welfare of the people is best promoted if government is hindered from functioning and friction generated among its parts. Such a theory assumes that government is fundamentally an evil and that the most important thing is to keep it out of mischief, even at the cost of rendering it expensive and ineffective. The opposite view—that government is a beneficial agency of social order, whose paralysis is a public misfortune—has led to indictments of the theory of checks and balances like that voiced by Woodrow Wilson: "The trouble with the theory is that government is not a machine, but a living thing. . . . No living thing can have its organs offset against each other as checks, and live. On the contrary, its life is dependent upon their coöperation, their ready response to the commands of instinct or intelligence, their amicable community of purpose. . . . There can be no successful government . . . without the intimate, almost instructive, coördination of the organs of life and action" (p. 56-57). Such criticism has not, however, led to any important practical effort to remedy the disadvantages resulting from the system of checks and balances, except in the field of municipal government, where efficiency and centralization of responsibility have been sought through the city manager plan.

CHEKA. See POLITICAL POLICE.

CHEMICAL INDUSTRIES. This term covers a varied group of industries, each impossible of exact definition and delimitation but significant as outstanding witnesses to the scope of the chemical phase of the industrial revolution. From the laboratory of the modern chemist has emerged a steady and increasing stream of new products and new methods of manufacture. Some have resulted in minute changes in old processes; some have created entire new industries and transformed or destroyed old ones; to an even greater extent chemical processes have penetrated into corner after corner of the industrial organization, bringing with them new standards and new methods of industrial and economic control. Over an increasing area the research laboratory has become the nerve center of production, the creator and critic of methods, products and policies, an indispensable intelligence service and commercial board of strategy.

The area of industrial enterprise thus affected by the chemical revolution is constantly growing. Hence a wide divergence of opinion and an enormous variation in usage exist as to the specific industries which are properly called chemical industries. Economists and other laymen uninformed on chemical matters are likely to be rather skeptical of the wide scope which the chemical technologist is wont to claim for the group. They would undoubtedly think of the old gunpowder industry as a chemical industry and scoff at the idea that the manufacture of glass or paper has a worthier claim to the title, even though the mixing of the ingredients in the powder industry involves no chemical interaction whatsoever while the making of glass and paper is a chemical operation in almost every detail. The term chemical industries has become too inclusive to be useful, simply because chemical technique and control are sweeping now suddenly, now gradually, but always progressively through industrial practise.

There is, however, considerable illustrative

value in a brief survey of the types of industry in which chemical operations are of dominant importance, those which use chiefly chemical engineering processes under the direction of trained chemists. The list will of course vary from period to period and country to country. For the United States at the present time it would certainly include the following major groups: metallurgical industries, iron smelting and the extraction of the non-ferrous, noble and rarer metals from their ores; fuel industries, the production of coke, artificial gas and charcoal, wood distillation, petroleum refining; heavy chemical industries, the manufacture of acids, alkalies, salts, fertilizers, electro-chemical products, cleansing and scouring materials; other inorganic chemical industries making glasses and enamels, ceramics, abrasives, refractories, lime, sand-lime brick, cement, industrial gases, printing and writing inks, matches; organic chemical industries including the manufacture of intermediates and dyes, explosives, perfumes, medicines and drugs, photographic materials, oils, fats, waxes, sugars and starches, accelerators and other chemicals for use in industrial processes, various alcohols and other solvents, paper, artificial silks such as rayon, oilcloth, linoleum, artificial leather, synthetic plastics, tanning materials, rosin and turpentine; and finally the colloid chemical industries producing glue and gelatin, gums and resins, paints and varnishes, tanned leather and rubber. In addition one might enumerate, but less easily classify, an even larger number of important chemical processes. It is clear that few significant generalizations can be made about the economic structure of such a heterogeneous group of manufactures, for each will have its specific history and problems. The effects of this increasing dominance of chemical processes in our industrial system can, however, be analyzed, and the study should throw considerable light on the nature of the modern industrial mechanisms.

The major part of this development has occurred since 1880; before that time chemical industries were largely extractive in character and their problems relatively simple. The subsequent growth has been rapid and world wide. Throughout the first three quarters of the nineteenth century the English alkali industry was the largest chemical industry in the world; then beginning about 1865 German chemical developments became of increasing importance, especially through the rapid expansion and organ-

ization of the dyestuffs and potash industries. In the United States the Eastman Kodak, the Aluminum and the Standard Oil companies came to the fore as representatives of this new revolution. Certain indicia of the rapidity of this development are available. Since all chemical agents or tools are either acids or alkalies the volume of production of such fundamental chemicals as sulphuric acid and soda ash furnishes a very good indication of the rate of adoption of chemical processing in industry. The figures are striking. In the United States, for example, the production of sulphuric acid, although begun as early as 1793 at the Harrison works in Philadelphia, had grown by 1875 to only 150,000 tons (50° Bé basis). But thereafter it trebled every ten years, amounting to more than 4,000,000 tons in 1914 and almost 7,500,000 tons in 1927. Similarly, before 1880 there was virtually no soda industry at all in the United States, the value of all soda products of domestic manufacture being less than \$700,000 and of imports about \$6,000,000. In 1927 over \$110,000,000 worth of soda products was consumed.

The origin of this new chemical knowledge and the methods of its application to industry furnish an outstanding example of the close relationship between modern science and modern economic organization. Individual chemical industries, sometimes successively but more often simultaneously, present three phases of development: the extractive, the synthetic and the creative. Whenever a chemical want is felt, man first tries to find a means of satisfaction directly appropriable in the natural universe about him. If he does not succeed sufficiently in that search he imitates the natural process, and ultimately, if further pressed, he creates a wholly new article. More frequently, however, these phases are all present at the same time or occur in no particular sequence. The chemists, pursuing strictly scientific ends, experiment with, and catalogue, the properties of every conceivable kind of substance. A relatively minor chemical invention has often helped to bring about economic phenomena of major importance. Thus the cyanide processes for the extraction of gold from its ores, invented in the early nineties, probably increased the available supply of the monetary metal more than had the discovery of any gold field.

The synthetic triumphs of the chemist have been most spectacular of all. Leblanc's production of artificial soda from salt; German and

English rivalry to be the first to substitute coal tar for madder as a source of alizarin; Bayer's success, after twenty years of research, in making the coal mines of Germany replace millions of acres of agricultural land in India as the source of indigo; Haber's process for capturing atmospheric nitrogen to make synthetic ammonia, invented just in time to render a belligerent Germany independent of Chilean saltpeter for her explosives and fertilizers—these are familiar stories.

The connection between each discovery and the advances of science is more often overlooked: such facts as that Leblanc was a pupil of Lavoisier, that Graebe was an assistant in the laboratory of Bayer or, similarly, that Perkins was an assistant of Hoffman and was bent on solving another scientific problem when he discovered the first coal tar dye, mauve, in 1856. For the most part it has not been the commercial and industrial but the university and scientific laboratories that have revealed new modes of synthesis. On the other hand, most of the discoveries of university research are in themselves of little use to industry. Many of them can never be commercially developed; many must wait years for utilization.

The increasing penetration of chemical processes into industry has forced the industrialist to seek for some less haphazard and more predictable method of utilizing the results of scientific discovery. Through the multiplication of industrial research laboratories he can in some measure direct the course of experimentation or at least be prepared to take immediate advantage of every new increase in knowledge. So we have the phenomenon of the highly organized, fully equipped chemical laboratory with its staff of young and eminent scientists taking its place as part of the business structure.

This introduction of the laboratory into the industrial system effects far more than an alliance of industry with science. It is one of the most important means by which the expert, the engineer, the technician, is coming to share a position of control in modern society. The lure of profits may suggest the ends and the goals of applied research, but the chemist points out the boundaries of the path to be followed.

The reach of this control is immeasurably greater than the scope of the authority of any one technician or group of technicians, whose actual influence may be very limited. For the very nature of the processes forces upon business and industry certain new characteristics. Specifica-

tion and standardization of processes successively call for, and are enforced by, the increasing penetration of chemical methods. Standardization paves the way for large scale production, the result also of several other features of all chemical industries. Most chemical operations must be carried on more or less continuously over long periods of time; hence the chemical industry is typically a continuous industry, and the problems of management involved lead frequently to large production units. Another important factor contributing to the many financial consolidations is the problem of patent relationships. Where combination has not proved feasible a degree of common action has been achieved through the establishment of research institutes working for a whole industry.

Chemical industries are, moreover, typically joint cost industries; frequently they develop through attempts to utilize by-products; always they involve problems of waste and possible salvage. There has been throughout a marked tendency toward both a vertical and a horizontal integration. In Germany the I. G. Farbenindustrie, in England the Imperial Chemical Industries, Ltd., in Italy the Montecatini Società per l'Industria Mineraria e Agricola, even before the war controlled the major portion of the output of heavy and organic chemical products of their respective countries. In the United States such companies as E. I. du Pont de Nemours, Inc., unite the production of an amazing range of chemical products. Since the war the tendency to cartellization and the use of licensing agreements has been accelerated by the economic dismemberment of Europe and the multiplying of tariff boundaries.

The chemical industries as a group, diverse as they are, thus present certain common problems of control. Other industries are more completely monopolistic, but in none are the potentialities of monopoly control greater. Not only does the growth of munitions industries and of all the other chemical industries which can now be so easily turned to the production of munitions augment the danger of new wars ever more horrible; the very complication of chemical processes makes a breakdown of the whole industrial system more likely and more catastrophic. The interpenetration of chemical processes in all industry is cumulative in its effect, and the more closely the business system becomes geared to such a series of products and methods, the more far spreading are the effects of crisis or expansion. This is something more than the complica-

tion of the business system. Fantastic as the picture of a single engineer bringing destruction to the whole of a city such as New York may be, it is true that the chemical engineer possesses a knowledge of unrealized and unknown power for good or ill. Many of the potentialities for good cluster about the fact that chemistry has created a new check on the workings of industry. Chemical methods may be complicated, they are always exact; here lies the possibility of a degree of public regulation of quality of product never before achieved. Only the first steps in such regulation have been taken and their extension involves an increasing complication of the social machinery. To harness, before it runs amuck, the power immanent and imminent in this new chemical knowledge is one of the major tasks of modern social statecraft.

CHEMICAL WARFARE. See WARFARE.

CHENG CH'IAO (Yü-chung) (1104-62), Chinese scholar. Although one of the most critical of Chinese historians his importance to native scholarship has only recently been recognized, the eighteenth century historian Chang Hsiuch'eng being the first modern writer to indicate his true significance. Living in an age devoted to

philosophic speculation Cheng Ch'iao advocated a return to factual scholarship. Recently discovered biographies in gazetteers of Fukien province throw new light on the scope and method of his investigations. Unfortunately only a fragment of his works has survived, of which the *T'ung Chih*, (General history), completed in 1161, is an example. In this work he expounded his idea of the scope of historical research. It should embrace the study of language, population, geography, the sciences, arts and social institutions. He insisted upon the continuity of history as opposed to the contemporary dynastic histories. The section dealing with the history of social institutions approaches in method of treatment the work of modern historians.

Cheng Ch'iao believed that knowledge should be gained by personal experience wherever possible and proposed that the natural sciences should be studied by means of actual specimens or, lacking these, by charts and illustrated drawings. He was the first Chinese to emphasize the importance of specialization in the sciences and the need for organization and classification of materials. These aims he also carried over into his study of ancient literature. In advocating the study of the *Odes* primarily in terms of their ancient rhythm and social and historical background Cheng Ch'iao injected a new principle into Chinese historical criticism which was not, however, fully carried out until the seventeenth century. He pointed out the late authorship of the preface to the *Odes* and of the inscriptions on the famous Stone Drums, attributing the latter to the third instead of the ninth century B.C.

ARTHUR W. HUMMEL

CHÉNON, ÉMILE (1857-1927), French jurist and historian. For over forty years Chénon taught the history of French law, exercising a profound influence on French jurists. He was a convinced Catholic and his religious inclinations determined the range of his work. A mediaevalist attracted particularly to the thirteenth century, he was led to innumerable archaeological and antiquarian investigations into local history. He studied especially the history of institutions in his native province, Berry, as in *Histoire de Sainte Sévère-en-Berry* (Paris 1888-89), *Les jours de Berry au parlement de Paris de 1255 à*

1328 (Paris 1921) and *Histoire de la paroisse de Vic-sur-Aubois et du prieuré de Bois l'Abbé en Bas-Berry* (Paris 1922). His studies of provincial history, which were both searching and extensive, illuminated the national development of French institutions; this is especially true of his clarification of the old French customary laws which are of particular importance in French jurisprudence. Indeed, Chénon regretted the influence of the Roman law in France. His greatest work, which he did not live to complete, was the projected general history of French law, *Histoire générale du droit français public et privé, des origines à 1815* (vol. i, Paris 1926; pt. i of vol. ii ed. by Olivier-Martin, Paris 1929).

Chénon participated directly in the religious life of France and from 1902 to 1905, before its condemnation by Rome, was active in the democratic movement called the Sillon (furrow). Of the numerous works in which he expressed his religious ideas the most significant is *Le rôle social de l'église* (Paris 1921).

OLIVIER-MARTIN

CHIERBULIEZ, ANTOINE ÉLISÉE (1797-1869), Swiss economist and political scientist. He was born in Geneva, where his family had settled after their emigration from France following the revocation of the Edict of Nantes. Chierbuliez was at first a lawyer and attracted some attention as author of the *Dissertation sur les causes naturelles du droit positif* (Geneva 1826). In 1831 he became a judge of the Civil Tribunal and four years later succeeded Rossi as professor of public law and political economy at the University of Geneva. He was elected a member of the Constituent Assembly and later of the Grand Council but after the fall of the Conservative Republican party in 1848 resigned all his offices and moved to Paris. Although he became a naturalized French citizen in 1850 he returned to Switzerland three years later as professor of political economy at the University of Lausanne and filled the corresponding chair at the University of Zurich from 1855 to 1869.

Chierbuliez was one of the most illustrious classical economists writing in the French language. The monumental exposition of his economic theories is the *Précis de la science économique*. Although the work was well written and more easily understood than that of John Stuart Mill it was not widely read and had little effect upon the course of French thought. Chierbuliez

wrote voluminously for the *Bibliothèque universelle. Journal des économistes et Dictionnaire d'économie politique*. His contributions cover money and banking, transportation, socialism, charity, theory of the entrepreneur, taxation, economic history and the history of economic thought.

Cherbuliez always remained an obdurate conservative and an irreconcilable opponent of mob rule, which he fought energetically in his native country and in France after the Revolution of 1848. In spite of his adherence to the school of thought which favored reduction of state activities to the minimum and in spite of his single tax doctrines Cherbuliez defended inheritance and private property, not on theoretical grounds but because he considered their advantages much superior to their disadvantages.

LOUIS VIGOUROUX

Important works: Précis de la science économique et de ses principales applications, 2 vols. (Paris 1862); *Riche ou pauvre* (Paris 1840, 2nd ed. Paris 1841); *Le socialisme c'est la barbarie* (Paris 1848); *De la démocratie en Suisse*, 2 vols. (Paris 1843).

CHERBURY, LORD HERBERT OF. *See* HERBERT, EDWARD.

CHERKASSKY, VLADIMIR ALEKSANDROVICH, PRINCE (1824-78), Russian statesman. He studied law at the University of Moscow and at an early age became interested in the problem of peasant emancipation. In 1847 he organized an informal group of his neighbors, the landed gentry of the province of Tula, to work out a program for the liberation of the peasants by the individual landlords, but the following year an order from the czar put an end to the activity of the group. Later in Moscow he became intimate with the Slavophiles, with whom he shared the view that the liberated peasants should be granted adequate land holdings, but against whom he urged the merits of individual rather than communal ownership of land. When the government of Alexander II began to prepare for peasant emancipation, Cherkassky submitted a number of lengthy memoranda on the subject. In the Tula official committee for the study of emancipation proposals he led in the attack on the conservative majority, which desired to restrict the scope of the reform and to reduce land grants to insignificant proportions. In 1859 he was appointed to the drafting board of the central commission charged with the analysis of suggestions made by the provincial commit-

tees and with preparation of the final draft of emancipation legislation. In this office he, together with Milyutin and Samarin, advocated an increase in the peasant land allotments and the provision of credit aid by the government to facilitate payments by the peasants. Cherkassky prepared for the commission the more important reports on the size and composition of peasant allotments and on rural self-government. Upon the promulgation of the reform laws in 1861 he served as the official mediator between peasants and nobles in his home district. During the Polish insurrection of 1863, when the government began the emancipation of peasants in Poland, Milutin was put in charge of the reform and secured the assistance of Cherkassky. Due to their combined efforts the reform in Poland was more liberal than in central Russia; the peasants received their land free from charges in favor of former owners.

In 1870 Cherkassky, as mayor of Moscow, was responsible for a municipal petition to Alexander II, urging a continuation of the liberal reforms, and was forced to resign when the petition was rejected. During the Russo-Turkish War of 1877 he was appointed head of the civil administration of liberated Bulgaria and was instrumental in instituting there a system of relatively democratic and autonomous local government.

CHERNYSHEVSKY, NIKOLAY GAVRILOVICH (1828-89), Russian publicist. Chernyshevsky, whose father was a clergyman, attended the theological seminary of his native Saratov and later entered the University of St. Petersburg, from the historico-philological faculty of which he graduated in 1850. He taught Russian literature for the next three years at the secondary school in Saratov and for several months at the Second Cadet School in St. Petersburg. Wishing to obtain a university appointment he defended in 1855 a thesis on "the aesthetic relations between art and life," which was welcomed as the manifesto of "publicistic literary criticism" championed earlier by Belinsky. Following Feuerbach, Chernyshevsky identified the beautiful and the real, distinguish-

ing beauty from mere perfection of form; he declared that art is a representation, explanation and evaluation of life and severely condemned the theory of "art for art's sake." Although he passed the examinations with distinction, he failed to receive the degree or the appointment because his views appeared blasphemous and revolutionary to the minister of education.

After 1853 Chernyshevsky was on the staff of the foremost radical monthly, *Sovremennik* (The contemporary), edited by the poet Nekrasov. He had early exhibited an unusual clarity and independence of thought and an extraordinary aptitude for languages; to these qualities he now added an amazing capacity for work. Each issue of the *Sovremennik* carried over fifty pages of his original contributions; among them were important monographs on Lessing and his age and on the Gogol period of Russian literature as well as many shorter pieces of literary criticism, characterized by a profound, sometimes prophetic, insight. At the close of the year 1857 he turned over the literary editorship to young Dobrolubov, in whom he detected great critical acumen, and devoted himself to economic and political problems, becoming the outstanding leader of the radical intelligentsia.

Although he was influenced by the rational socialism of the French utopians, particularly Fourier, and by the utilitarian ethics he remained an independent and original thinker. He recognized the importance of economic factors and of social stratification and anticipated Karl Marx on several important points. In the extensive additions to his translation of J. S. Mill's *Principles of Political Economy* and in other works he contributed original discussions of the social value of large scale production and division of labor, of the effects of technical progress, of the antagonisms between land, capital and labor and their effect on production, of concentration of wealth and proletarianization of the masses, of the Malthusian law of population in different economic systems. He envisaged the desirable economic order somewhat in the spirit of Proudhon and Louis Blanc as a system of voluntary associations of producers assisted by the government. In several articles on peasant emancipation he advocated the preservation of the village community as a bulwark against "the scourge of proletarianism"; to this extent he was the father of Russian populism. He refuted many of the stock objections to communal land holding which were brought forward much later, but he never shared the Slavophile delusion that

the village community was an indigenous institution peculiar to the Slavs. In an article on the "anthropological principle in philosophy" he championed the naturalistic materialism of Feuerbach and Bichner as the only philosophy compatible with socialist humanitarian sympathies.

Chernyshevsky exerted an impressive influence, and thus with the beginning of the reactionary period in 1862 he was subjected to a series of unusually severe government persecutions which were based on trumped up charges. After being imprisoned for two years in a fortress he served a sentence of seven years of hard labor and for twelve more years lived in exile in the far north of Siberia. In the fortress he wrote a novel *Chto dela? (What Is to Be Done?)*; translated into many European languages, English translations New York 1886 and Boston 1886) which inspired two generations of Russian youth. Devoid of literary merit but imbued with the spirit of noble humanitarianism, this half utopian novel preached an idealized version of utilitarianism and the establishment of producers' cooperatives. Much later Chernyshevsky published an article on "the theory of the beneficial effects of the struggle for existence," in which he castigated social Darwinism as a piece of bourgeois apologetics. At the end of his life he translated twelve volumes of Weber's universal history and appended to them independent essays on historical and related subjects. Despite the fact that for a long time after his imprisonment the censorship forbade even the mention of his name, his reputation in Russia remains undiminished even to the present day.

I. V. DIONEIO-SHKLOVSKY

Works: A ten-volume collection was edited by his son (St. Petersburg 1906). Since 1917 a number of hitherto unpublished writings appeared in scattered publications in Russia; the most important of them is the diary for 1848-53 (Moscow 1928). The more important translations of Chernyshevsky's works are: *L'économie politique jugée par la science*, tr. by A. Tvertinov and C. de Paeppe (Brussels 1874); *Osservazioni critiche su talune dottrine di G. Stuart Mill (Lavoro e capitale considerati come elementi della produzione)*, Biblioteca dell' economista, 3rd ser., vol. ix, pt. 1 (Turin 1886); *La possession communale du sol*, tr. with a biographical notice by E. Laran-Tamarkine (Paris 1903); *Lettres sans adresse (sur l'abolition du serfage en Russie)* (Liège 1874).

Consult: Plekhanov, G. V., N. G. Tschernyshevsky (Stuttgart 1894); Sticklov, Yu., N. Tschernyshevsky: *ein Lebensbild* (Stuttgart 1913). A bibliography of Russian works about Chernyshevsky is available in the Granat encyclopaedia, vol. xlv, pt. iii (Moscow 1920) p. 805-06.

CHEVALIER, MICHEL (1806-79), French economist. The economic doctrines and program formulated by Chevalier when in the period following his graduation from the École Polytechnique he was editing the Saint-Simonian review, the *Globe*, remained, despite his early break with *Enfantin* and the other extreme doctrinaires of the *Menilmontant* "family," the foundation of his later work. He returns to them in his *Lettres sur l'Amérique du Nord* (2 vols., Paris 1836) and his *Histoire et description des voies de communication aux États-Unis* (2 vols., Paris 1840-41), which on the basis of his two-years travel in the United States idealize the civilization of the young country as the embodiment of Saint-Simonian ideals. His lectures (published as *Cours d'économie politique*, 3 vols., Paris 1842-44; 2nd ed. 1855-66) at the Collège de France, where he was appointed professor of political economy in 1840, are an elaboration, with a broadened, more experienced viewpoint, of the same themes. One of his last works, *Introduction aux rapports du jury international de l'Exposition Universelle de 1867* (Paris 1868), is but another reiteration in condensed form of his consistent economic credo.

Chevalier, both as a theorist and in the realm of practical statecraft, was the outstanding champion of industrialism in France. Productive power with a resultant accumulation of capital represented to him the surest guaranty of the welfare of society. Disclaiming sympathy with materialistic philosophy he extolled the machine rather as the liberator from oppressive drudgery and identified social progress with the expanding capacity of the human intelligence to dominate the material environment. Liberty he conceived of in terms of society as a whole rather than of the individual or the class; equality, as an equality of opportunity to advance in a chosen career. In place of class struggle instigated from below he favored alleviation of poverty from above and by increased production and accumulation of capital the gradual elevation of the less fortunate classes. The basis of his repudiation of the program of Louis Blanc and the advocates of the "ateliers nationaux"—which cost him, temporarily, his chair at the Collège de France—is set forth most clearly in his *La question des travailleurs* (Paris 1848) and *Lettres sur l'organisation du travail* (Paris 1848).

To the fostering of a highly industrialized society the state should devote its maximum energy, discontinuing, as a prelude to a new era of international peace, its military and naval

activities. As essential factors in this process of industrialization Chevalier advocated: first, a tremendous increase in the media of communication—railroads, highways, canals, isthmuses, tunnels, public works of all kinds; second, an expansion of banking facilities and credit with removal of unjustified restrictions; and, finally, the development of an adequate educational system emphasizing especially professional and technical training. From the beginning of his career Chevalier foresaw the great civilizing role of the railroads in breaking down departmental and national barriers. In various official capacities he was instrumental in forwarding their spread throughout France. His internationalism expressed itself also in his free trade campaign, which beginning in 1852 culminated in the famous Anglo-French commercial treaty of 1860 negotiated by Chevalier and Richard Cobden. He was prominently identified with the international expositions of 1862 and 1867 and in 1869 was elected president of the International League for Peace. His belief that international exchange would be most effectively conducted under a system of monometallism is set forth in *Monnaie* (Paris 1860).

ROGER PICARD

Consult: Labrousse, P., *Michel Chevalier et ses idées économiques* (Paris 1939), including bibliography, p. 164-68; Weill, G., *L'école saint-simonienne, son histoire, son influence jusqu'à nos jours* (Paris 1896); Courtois, A., "Notice sur la vie et les travaux de Michel Chevalier" in *Journal des économistes*, vol. xlv (1889) 455-76; Bastiat, F., *Cobden et le libre échange* (Paris 1845); Wallon, M., *Les saint-simoniens et les chemins de fer* (Paris 1908).

CHEYSSON, ÉMILE (1836-1910), French social economist and reformer. He was born at Nîmes and, like many other French economists and sociologists, began his education in the exact sciences at the École Polytechnique. Until 1867 he was a successful engineer in the service of the government. In that year he met Frédéric Le Play, who had charge of the organization of the Exposition Universelle in Paris, and soon became his disciple. Cheysson contributed nothing new to sociology or economics, but he exercised an enormous influence in the field of social legislation. He shared Le Play's strong religious and paternalistic attitude and like him he stressed the importance of statistical studies and detailed monographs concerning the families of working men. Although he saw very clearly the necessity for social reform his point of view was basically that of the liberal indi-

vidualistic school. He feared that governmental intervention might weaken the individual's initiative, and this explains his emphasis upon organizations for social welfare rather than upon legislation. He was instrumental in organizing more than twenty societies of municipal, regional and national scope, of which the more important are the Musée Social, the Alliance d'Hygiène Sociale and the Société d'Économie Sociale.

MOSES J. ARONSON

Works: The more important of Cheysson's writings are contained in *Oeuvres choisies*, 2 vols. (Paris 1911), with a complete biography and bibliography. See particularly "Mon testament social," vol. ii, p. 1-17. *Consult:* Colson, Clement, "Notice sur la vie et les travaux de M. Émile Cheysson" in *Académie des Sciences Morales et Politiques, Séances et travaux*, vol. clxxx (1913) 153-87.

CHICHERIN, BORIS NIKOLAYEVICH (1828-1904), Russian political and social philosopher. He was professor of constitutional and administrative law at the University of Moscow until 1868, when he retired to his country estate. For nearly half a century he was the most important representative of Hegelian philosophy in Russia. In his works on Russian administrative and legal history, on the history of European political theory, on political science and philosophy, he attempted not only to give concrete body to Hegelian schemata but also to refine and develop them. Thus he substituted a fourfold scheme for the dialectic trend of Hegel: the thesis is opposed by two antitheses which are not completely resolved in the synthesis. Also, to Chicherin the highest stage of the dialectic process was not the "absolute spirit" (religion and art) of Hegel, but the "objective spirit," the ethos, the "ethical realm of the free will." That the influence of Kant was superimposed on Hegelianism is even more clearly shown in Chicherin's social ethics. "The community achieves its purpose and value only through the individual. . . . Institutions exist for the individuals and not individuals for institutions." The same ethical individualism is reflected in Chicherin's complete separation of law from morals, in his defense of unconditional individual property, in his strong opposition to any intervention by the state for the protection of the weaker members of society. Politically he was an old fashioned liberal and paved the way for the Russian Constitutional Democratic party (*Kadet*), although he did not live to see it formally organized. His intellectual in-

fluence upon the party did not prevent it, however, from shifting gradually to a position of positive neoliberalism. Chicherin was not successful in his self-appointed task of combining the ethical objectivism of Hegel with the Kantian autonomy of practical reason. He overlooked the significance of Hegel's "concrete whole" when in following the atomistic mode of thinking he attempted to substitute for it the notion of the abstract universality of the law.

GEORGES GURVITCH

Important Works: *Oblastniya uchrezhdeniya Rossi v 17 veke* (Provincial administration of Russia in the 17th century) (Moscow 1856); *Opiti po istorii russkogo prava* (Essays in the history of Russian law) (Moscow 1858); *Istoriya politicheskikh ucheniy* (History of political doctrines), 5 vols. (vols. i iv Moscow 1868-77, vol. v Moscow 1902); *Kurs gosudarstvennoy nauki* (Course in political science), 3 vols. (Moscow 1804-98); *Sobstvennost i gosudarstvo* (Property and the state), 2 vols. (Moscow 1882-83); *Filosofia prava* (Philosophy of law) (Moscow 1900).

Consult: *Encyclopaedia* of Brockhaus and Efron (in Russian), vol. xxxviii (1903) 887-901; Gurvitch, G., "Die zwei grössten russischen Rechtsphilosophen: Boris Tchitcherin und Vladimir Ssolowjeff" in *Philosophie und Recht*, vol. ii (1922-23) 80-102.

CHILD, JOSIAH, BARONET (1630-99), British merchant. He was born in London, the second son of Richard Child, merchant. Having amassed a large fortune Child became a director and later governor of the East India Company, whose affairs he conducted over a long and stormy period in a despotic and not over-scrupulous manner. His great wealth and capacity made him a dominating personality in the finance of the second half of the seventeenth century.

His *New Discourse of Trade*, the most important of his works, had several stages before it reached final form. The first draft was his *Brief Observations Concerning Trade and Interest of Money* (London 1668), followed the same year by *A short Addition to the "Observations Concerning Trade."* In the year 1669-70 he wrote ten additional chapters and the complete work was issued as *A Discourse about Trade* (London 1690). In 1693 the same work with little variation except an introduction of twenty pages, "The Publisher to the Reader," and the name of Child on the title page, appeared as *A New Discourse of Trade* (new ed. London 1775). Child's fifteen reasons for the prosperity of Holland contain many suggestive ideas, although his argument that a low rate of interest is the cause of national prosperity cannot be sustained. He

advocated freedom of trade (except in the East Indian trade), poor law reform, negotiable bills, better education, etc.

Child was essentially a man of action. Because he was the wealthiest Englishman of his time and the most prominent figure in finance and foreign trade, the ideas in his book are interesting as evidence of contemporary business life and opinion. Few seventeenth century writers who had practical knowledge of big business published their views about trade, and his opinions naturally attracted great attention. We read that the brokers on 'Change watched his smile or his frown on arrival to mark prices up or down. But his numerous works are hardly a connected argument upon any aspect of theory or of any germinal significance or originality.

HENRY HIGGS

S., "Bibliography of Sir Josiah Child" in *British Library of Political Science, Bulletin*, no. xiv (1921) 15-17; Helander, Sven, in *Weltwirtschaftliches Archiv*, vol. xix (1923) 327-29; Macaulay, T. B., *The History of England from the Accession of James the Second*, ed. by C. H. Firth, 6 vols. (London 1913-15) vol. v, p. 2096-2103; Scott, W. R., *The Constitution and Finance of English, Scottish and Irish Joint-Stock Companies to 1720*, 3 vols. (Cambridge, Eng. 1910-12) vol. i, p. 319-23, vol. ii, p. 140-60.

CHILD, LYDIA MARIA (1802-80), American author and reformer. She is best known for her enthusiastic and spirited efforts toward the abolition of slavery, although she interested herself

also in the status of women, the treatment of the Indians, the advance of temperance, the peace movement and the history of the development of religious ideas. Her early historical novels and her writings in the *Juvenile Miscellany* (1826-34), a periodical which she edited, gained a considerable public, much of which she lost upon the publication of *An Appeal in Behalf of that Class of Americans called Africans* (Boston 1833). Mrs. Child continued, however, to use her gifted pen in educating the North concerning the evils of slavery. Her *Anti-Slavery Catechism* (Newburyport 1836) and *The Evils of Slavery and the Cure of Slavery* (Newburyport 1836) slowly overcame the hostility roused by her first work on the subject and regained for her a body of readers. Probably the most influential of her writings, although at the same time one of the most ill considered, was a letter to John Brown, which was printed along with the correspondence with Governor Wise and Mrs. Mason of Virginia evoked by it, and ran to some 300,000 copies. By her writing and by her personal influence on her husband, David Lee Child, and on Charles Sumner, Henry Wilson and Governor Andrew, she earned Whittier's tribute that no man or woman had rendered more substantial service to the cause of freedom.

CHILD WELFARE is a term which connotes the general well-being of the child. In all ages this has depended principally on the social valuation of children and the care accorded to them. At the present time the child is considered an important social unit and is held to be en-

titled to all that makes for healthy living—sufficient recreation, schooling adapted to his natural learning methods, intelligent home care and the right to develop his abilities to their fullest extent. These may be assured to the more privileged child by his own parents, but children

of less fortunate or less responsible parents and children who are orphaned or have been deprived of their natural guardians may have to depend for them, at least to some degree, on the organized child helping services of the community.

In addition to the many types of family situation which necessitate outside aid there are many other reasons for the existence of child helping services. Among the more obvious are patriotic interest in the conservation of human resources, fear of crime growing out of child neglect, obedience to religious injunction, pity in the presence of helpless suffering, the need to satisfy thwarted parental feelings, desire to extend the activities of a political, religious or fraternal organization, and interest in the scientific study of physical and mental growth or in the building of a more efficient social order. John Dewey formulated what is perhaps the most socially minded type of motivation for child welfare activities when he said that "what the best and wisest parent wants for his own child, that must the community want for all its children."

Child welfare activities are of many types. In some instances financial assistance is extended to the parent to enable him to continue the care of his own children, usually with some measure of supervision. In other instances aid is rendered directly to the child by providing him with foster care in institutions or families either for short or for extended periods. The activities include also professional services such as those offered by child health clinics and infant welfare stations; care of dependent, handicapped or delinquent children; safeguarding of child workers and of the child's interests before the law; adjustment of problem children; and attempts to provide children with recreation and specialized educational facilities. Research, including both medical and social surveys, has been of inestimable value to the development of all these activities.

The amount of attention given to the various aspects of a child's well-being reflects the ideals and social pressures in any given society. With subsistence precarious, food and shelter are boons; in an intensely religious age, religious instruction is of first importance; in an age of technology, scientific education assumes large proportions; in complex environments, the insuring of physical health and a stable mental adjustment are accounted among the most essential services to children. Very recently the multipli-

cation of studies and services dealing with fractional aspects of the child's personality has found a corrective in the Gestalt psychology, which emphasizes the need of continuously taking into account all aspects of the child's well-being and dealing with "the whole child," not some isolated phase of his development.

The quality of the care accorded to children among primitive peoples is very difficult to determine. Earlier popular writers were inclined to enlarge upon such practises as child sacrifice, infanticide and child slavery among primitive and semicivilized tribes. Evidence collected by more sympathetic students was likely to be prejudiced in the opposite direction. Infanticide, however, and similar practises need not necessarily be regarded as evidence of continuing parental attitudes of selfishness and indifference. To tribes frequently on the march or those whose food supply is scanty children are a burden, and measures for limiting the increase in population may be stringent. But among races in a higher state of civilization or under less severe economic pressure children are often greatly prized for their economic and prestige value as possessions. Almost everywhere some children are wanted because they assure to the mother security in her position as a wife, and to the father the maintenance of rites for the dead and continuance of the ancestral line.

With regard to the child's position among primitive peoples, emphasis is usually given to the complete subservience of the child to the adult—the necessity of his fitting into a rigid social scheme and deferring unquestioningly to the rule of the elders, at the risk of severe punishment or death. On the other hand, it is pointed out that not a well defined plan of discipline but momentary irritation may be the ordinary cause of his chastisement, and that sometimes for the immature child there are no tabus. He is of such slight consequence that his acts do not matter. Indeed, one of the characteristics of treatment of the young, according to Miller (*The Child in Primitive Society*, New York 1928), is the failure to regard them as completely human. The child runs about unnoticed "like a little dog," often has no name until the age of initiation or perhaps has a generic title not differentiating him from material objects.

Initiation means the individualization of the child, frequently his naming and the determining of his animal totem. The severity of the rites is a preparation for the later hardships of the

hunt and of war, while the passing on of the tribal traditions, with their references sometimes to a still more ancient and now unintelligible tribal past, marks him as an adult trusted to conform to the folkways of his group. The boy's education is commonly instruction in fishing, hunting, swimming and the enduring of cold and pain; also in performing his part in the economic activities of the tribe. The girl learns to plant and weave and is often burdened with the care of younger children, when these are not merely left to fend for themselves. Child labor, as Chamberlain points out (*The Child and Childhood in Folk Thought*, New York 1896), reaches far back into primitive society, for these child nurses and young workers were often kept severely to their tasks. Frequently, however, there is ample opportunity for play, and this may take elaborate forms. It is usually in imitation of grown up activities but sometimes, under supervision by the elders, it takes the form of competitive games designed to strengthen endurance.

When normal care for the child within his own family is not possible, the expedients followed by early societies vary from promptly killing the child to providing him with better care and education than would otherwise have been his lot. Imitations of family relationships are set up in many ways, such as adoption, godparenthood, foster parenthood and legal guardianship. Adoption, which has an important place among the customs of primitive peoples, is provided for as a well defined contractual relation under the Babylonian Code of Hammurabi. Wardship under the Roman law was very seriously regarded.

Throughout the long period preceding the development of modern science two of the strongest forces among the medley of those which shaped the behavior of communities and families toward children were those of mutual aid and charity. From very early times, through the Middle Ages and even down to the present, individual families in trouble have been relieved through the practise of mutual aid, which among simple peoples is the rule. The practise of charity, one of the roots of modern child welfare, also reaches far back into history, particularly in the form of concern for orphans. Greece in the age of Plato provided funds for soldiers' orphans and free medical service for poor children. The famous *pueri alimentarii* in Rome at the period of the empire was a special semi-governmental service for the charitable mainte-

nance of the children of indigent citizens. The early Christian church set up parochial services which provided for assistance and care of children, and throughout the Middle Ages the church organization continued to be the principal agency through which charity, including aid to children, was dispensed. Japanese history records that charitable interest in the care and protection of children was present a thousand years ago.

From the emergence of civilization in Babylonia, Egypt, Greece and Italy to the beginning of the modern period in England there were in general three great classes of society: agricultural populations working either as slaves, serfs or tenants, with the children usually sharing the meager life of their families; guildsmen, both artisans and merchants, with their children or those adopted by, or indentured to, them following in their footsteps; and the ruling and professional classes, who often enjoyed a life of some cultivation but were so lacking in scientific knowledge that the lives and health of their children were often precarious. In general each of these groups gave its children such care and education as seemed necessary to enable them to maintain themselves in the social group into which they were born. The prevalence of the caste system among the Hindus and to a less extent among the early Egyptians strongly conditioned the status of children among these peoples, and even in Athens and Rome formal education beyond the learning of a trade was largely confined to children of the ruling classes.

There is little in classical or earlier literature that deals with the everyday life of the child. Such education as existed, particularly where, as in Athens, women occupied a socially inferior position, was available mainly to boys. The Athenian schools gave training in music, gymnastics and mathematics with the purpose of furthering a harmonious development of body and mind, and Greek youths were encouraged to perfect themselves physically through sports and games. The scheme of education elaborated by Plato allowed for differences in training according to the child's future place in the state, but this was a purely theoretic program. Both Sparta and Rome regarded the child as material for citizenship, to be trained primarily for future service to the state. Roman law gave the father or head of the household practically unlimited authority, *patria potestas*, over all children of the family group. He could abandon them to exposure, imprison or kill them or sell them for

slaves beyond the Roman borders. This power, though virtually unchecked by law, was in practise curtailed by religious considerations, family affection, public opinion and the power of the Roman censor. Roman education in the latter years of the empire became highly formalized, and the rise of scholasticism in the Middle Ages still further removed education from concern with everyday life. The attitude of scholasticism in holding the child to be a miniature adult, an attitude found equally among some of the most primitive savage tribes, was inimical not only to the progress of education but to any attempt to understand the real nature of the child and to evolve methods adapted to promote his welfare.

The intellectual awakening that came with the Renaissance resulted by the time of Francis Bacon in clear intimations of the value of scientific knowledge in the search for human welfare. Among the earliest applications of scientific theory to child study were the writings of Comenius on education. His idea that the processes of education could be pleasurable and not a torture to children was in itself an epochal change in thought. Hermann Francke at Halle stands out not only as an advanced educationalist but also as the founder of educational-charitable institutions. In America, Benjamin Franklin likewise aimed at doing something more than feeding and sheltering children when in 1751 he opened the Academy and Charitable School in the Province of Pennsylvania, now the University of Pennsylvania.

With the spread of scientific and humanist ideas, the latter half of the eighteenth century saw profound social changes which inaugurated the era of democracy. With it came the acceptance of a belief in the rights of man and in the equal right of all children to education, health and happiness. Rousseau, with deep and contagious emotionalism, expressed his profound sympathy with the mass of people and with children in books which strongly influenced the development of child welfare. His *Émile* has been called the "Children's Charter." It marks the first complete modern expression of the ideas that human life and happiness are largely made or marred in childhood, and that there are scientific ways and means to be applied in the management of children. Rousseau held that the unhampered development of his nature, his powers, his inclinations was due every child. The educational methods advocated by Rousseau are still under debate, but his appreciation

of the dignity and worth of each child's life has been a dynamic influence in child welfare work. Among those who did most to realize Rousseau's theories were Pestalozzi, Herbart and Froebel. In England, Robert Owen effected some notable advances in educational method in his New Lanark experiments, begun in 1800.

Against the background of this new humanitarianism, with its acceptance of equalitarian ideas and its advances in educational theory, stand out boldly the exploitation and neglect of children and the many confusions and abuses which resulted from the rapid growth of industry and urban centers in the nineteenth century. No social standards applicable to the factory system existed to safeguard working children. They were brought into the factory at a very early age, required to work almost unlimited hours and sometimes made to "live in," sleeping as well as working at the factory. Even the paternalism that made the apprentice under the guild system almost a part of the family unit was lacking. Dependent children lived frequently in almshouses under conditions usually depressing and often degrading and were sometimes apprenticed in gangs to the factory owner, with no further thought to their protection. The method called "baby farming," by which large numbers of children were boarded with a careless custodian, resulted in a tragically high death rate, as did also institutional care of babies.

The program of modern philanthropy, which had its roots in the ancient practise of charity, developed not only out of the challenge of these conditions but also from a recognition of the contribution which modern medical progress and methods of scientific research could make to human welfare. For its financial support the new philanthropy could turn to the rapidly accumulating wealth in Europe and America, which could both pay taxes for public services and endow private funds; and the reservoir of spontaneous human generosity which earlier showed itself in mutual aid could be drawn upon for the democratic financing of welfare activities. Humanitarian agitation evoked by the intolerable conditions found in the factories, slums and sweatshops of Europe and the United States led to early monumental surveys of social conditions and to legislation designed to regulate these evils.

The improvement of the treatment of children in conflict with the law has been an important aspect of the development of child welfare during the last century. The law early took cog-

nizance of the child in the matter of guardianship, property rights and discipline but was slow to protect him adequately against cruelty, neglect or exploitation by industry and to differentiate between the child offender and the adult criminal. While children under seven were recognized as not endowed with adult powers of discrimination and hence not liable for their acts and children between seven and fourteen were presumed to be without criminal intent, those over this age were subject to the same criminal jurisdiction as adults. Early efforts to help these children took the form of confining them after conviction apart from adult criminals. Probation was also used to some extent in place of commitment to an institution. Later came the establishment of the special courts to hear children's cases which are now found in the majority of states in the United States. There is still some doubt in many places as to the exact status of the child offender before the law, but in general his treatment is now based on the desire not to punish him but to aid him in overcoming his handicaps of personality and social environment.

The desire to protect children from cruelty and neglect led to the organization of societies for this purpose, empowered by the legislatures to cooperate with the police. Illegitimacy laws have been revised to give a greater measure of protection to children born out of wedlock; and the contractual powers of the child have been limited, with restrictions on child marriages.

Child labor agitation has gradually set up legal restrictions on the employment of minors, until at present the legislative battleground for compulsory school attendance has moved up to the ages of fourteen to sixteen. England is accordingly undertaking to raise the school leaving age for the whole nation to fifteen as a measure of unemployment relief. In the United States continuation school requirements, by creating in employers a reluctance to hire children, even those having working papers, have indirectly tended to make grammar school graduates more inclined to continue their regular education. Trade school courses are being more closely related to methods actually used in industry through the cooperation of labor leaders, employers and educators. Juvenile placement work within schools or through public exchanges is coming to be recognized as necessary to keep children out of blind alley jobs and prevent the high rate of turnover usual among young workers.

Many types of child health activities have made progress in recent years. Among the most conspicuous are the various aspects of infant welfare that have received attention in the effort to lower the infant death rate. The death rate from tuberculosis, which formerly had a high incidence in childhood and youth, has also been greatly lowered through the antituberculosis campaign, by means of preventoria, fresh air schools, nutrition camps and general educational activities. During the last few years the diphtheria death rate among children has been sharply reduced through private and public efforts, by means of health demonstrations, traveling clinics and the like. Nutrition work and the provision of school lunches have also made progress. Behavior clinics for preschool children, visiting teacher work with problem children in the schools, child guidance and mental hygiene demonstration work, with psychiatric clinics for children of all ages, indicate a new awareness of the need to provide for the child's adjustment difficulties as well as for his physical welfare. They are in the nature of preventive measures to reduce mental disease and to limit juvenile delinquency, which is so frequently the forerunner of crime. Not only the subnormal and the handicapped but gifted children too are now being studied and special classes organized for them with curricula sufficiently full and varied to meet their needs.

For the normal child organized and well adapted recreation is thought to be the best preventive of maladjustment. Home recreation, with all the family participating, is being definitely promoted by the Playground and Recreation Association of America, as are settlement classes, supervised public playgrounds and backyard gardens. Such organizations as the Boy and Girl Scouts, Camp Fire Girls, Pioneer Youth and other youth organizations stressing athletic activity are all positive forces tending to prevent juvenile delinquency and to promote physical health and a well rounded adjustment of the personality. Improved methods in education have also done much to give the child his full chance. Nursery schools for very young children have developed, supplementing the earlier kindergarten, and experimental schools of many types have been established for children of all ages. Progressive education is making headway toward "the child-centered school," while innovations in educational methods are reaching even to the universities.

The movement for dealing with child dependency on the basis of the family unit has had a wide acceptance. Its most striking developments are the family allowance method of wage payment, in use in European countries, and the spread of mother's pension legislation, now in effect in nearly all states of the United States. The promotion of home recreation and the movement for parental education are other aspects of the endeavors to maintain the home. Where the child's own family has been broken up an attempt is made to place him in a boarding home rather than in an institution, and this practise has been extended wherever feasible even to problem children, cardiacs, cripples and small infants.

Child welfare work originally concerned itself primarily with two large age groups, infants and young children, with attention also to children who were employed. Recently the tendency has been toward a finer discrimination of age groups with special services for each. Among the services for infant children are prenatal clinics, maternity welfare work and well baby clinics. The child of preschool age has of late years claimed special attention from educators, psychiatrists and physicians. Nursing schools, habit clinics, mental testing and detailed studies of various aspects of behavior for very young children have been developed. Educators after decades of theorizing about the nature of the child have now set themselves to study his actual behavior, as a basis for new educational experiments. The gang age, when various important social patterns are first developed and discipline becomes a problem, had until lately been neglected as one of the more undistinguished periods of childhood. Recently a number of studies have centered attention on these years, and recreational programs suitable for the gang age are being developed. The critical years of adolescence had also been accorded only a tiny fraction of the study given to childhood in general, but now their many subtle problems are becoming a focus for research by sociologists, psychologists and religious workers.

There are many organizations both governmental and private concerned directly with children, whose activities touch child welfare at many points, as well as other agencies dealing with special fields, such as probation or mental hygiene. The organized social welfare activities of the various churches, such as neighborhood houses, homes for wayward girls, religious youth groups and the student in industry movement,

have affected children and young people in many ways.

The federal Children's Bureau carries out an extensive program of research and education. It cooperated with the states in their administration of the Sheppard-Towner Act and has made many studies of infant mortality, nutrition, time required by mothers for baby care, children's protective laws, child labor and international progress in child health and protection. It also publishes charts, record forms, diet programs and other well baby material. It has effectively aided the temporary commissions which a majority of the states have set up in recent years to study their laws relating to children.

A growing number of states have bureaus or departments of child welfare differing from the federal bureau in that their functions are not so much research as enforcement and supervision. Institutions for delinquent or handicapped children, the administration of child labor and illegitimacy laws, and the care of dependent children may be under their charge or supervision. In a few states there are county boards of child welfare in charge of local administration, with supervision and maintenance of standards remaining the function of the state boards.

National voluntary organizations concerned with child welfare have shown rapid growth in recent years. The Consumers' League, the National Child Labor Committee and the local societies for the Prevention of Cruelty to Children have worked for protective legislation. The Child Welfare League of America, which is a federation of child caring agencies, the Child Study Association, the National Child Welfare Association, the American Child Health Association, the child guidance demonstration committee of the Commonwealth Fund and many other organizations, local and national, are furthering the application of scientific knowledge to the individual child. The National Congress of Parents and Teachers, with a membership of thousands of local parent-teacher associations throughout the country, is using in some of its local groups the best modern methods of adult education. The Progressive Educational Association makes available the findings of the newer experimental schools in applied child psychology.

The Children's Foundation of Valparaiso, Indiana, has set a high standard in publication. The Iowa Child Welfare Research Station at the University of Iowa has since 1917 carried on an extensive program of research and publica-

tion. The Institute of Child Welfare at the University of Minnesota is conducting an elaborate and practical program of home education in social hygiene for parents and children, with detailed recording methods. The Child Development Institute at Teachers' College, Columbia University, is initiating research on the behavior of children of preschool age. The Children's Foundation of Michigan, organized in 1929, the Brush Foundation in Cleveland, the Institute of Child Welfare at the University of California and St. George's School for Child Study at the University of Toronto are among other organizations of the kind. The White House Conference on Child Health and Protection of 1930, following earlier similar conferences, was designed to evaluate progress and to set up new standards of social activity for the benefit of the child.

Under the League of Nations a Child Welfare Committee conducts research and compiles national laws relating to children. It has studied such topics as the repatriation of foreign children, infant mortality, the family allowance system, child marriage and child labor laws. Recently it extended its program to consider delinquency, illegitimacy and the influence of motion pictures. At various times since 1883 international congresses have been held dealing with the welfare and protection of children. In 1928 a congress was held in Paris under the auspices of the League of Red Cross Societies, the International Infant Welfare Union, the International Child Welfare Association and the Union Internationale de Secours aux Enfants. This last organization was started in 1920 as the "Save the Children Fund," and by the end of 1927 had distributed £4,000,000 for the care of destitute mothers, infants and children in many countries. As an outgrowth of a pan-American congress held in 1924 the American International Institute for the Protection of Children was founded at Montevideo to organize national child welfare activities in the western hemisphere. The sixth Pan-American Child Welfare Congress met in 1930.

The World War, with its great depletion of human resources, turned the attention of most European countries to the urgency of reducing the infant death rate. The increased number of working mothers caused many countries to adopt, if they had not already done so, a system of financial assistance to women at the time of confinement, in addition to a fixed amount of

time off from work. Mothers were also encouraged by nursing premiums or the provision of free lunches to nurse their babies; and the need for better midwifery received much attention, particularly in England. Convalescent homes and nursery schools have also had a widespread development. In France, Italy, Japan, Poland and some other countries, as a result of the extensive employment of working mothers, the law requires employers to set aside a room for nursing mothers where they may care for their infants at certain times of the day.

The German constitution of 1919 is a charter of children's rights, under which extensive welfare activities have been carried on. The state and local Jugendämter, or juvenile boards, have very broad powers, supervising mothers' consultation centers, boarding out and guardianship of illegitimate children. There is in Germany a total of 2,300,000 children dependent on public or private charity. In Norway child welfare councils in each municipality replace the courts in jurisdiction over children below the age of sixteen; and the child welfare boards in Sweden and local councils of guardians in Denmark carry on similar activities. Norway and Sweden also have advanced laws on the subject of illegitimacy and aid to unmarried mothers. Austria has left the financing of infant welfare work largely to private funds or local government resources. Much educational work has been carried on there through traveling health centers. Czechoslovakia, which has had a rising tuberculosis death rate, is now well supplied with convalescent homes. Inspection of children by school doctors is the rule, a health measure which is becoming widespread in Europe and Australia. Social insurance in Russia covers all workers, but mothers who are brain workers are allowed less time off before and after confinement than those doing heavy physical work. The Soviet Republic is working to extend children's health services and sanitarium in Russia, and free school lunches have been instituted. Many model homes for children have been established. A national mental hygiene service is now open to persons of all ages, although its extension is hampered by a shortage of training schools for psychiatric workers. Young Social Aid Brothers and Sisters guard against the exploitation of child workers in small industries. Italy is taking active measures to reduce maternal mortality and carrying on extensive research to that end. Instruction in the care of babies is given in normal schools.

The Australian states and New Zealand have an excellent system of children's courts for dealing with juvenile delinquents. Baby clinics and health services have been widely developed, and medical examination of school children, while not required in all states, is fairly general. The boarding out of dependent children has been well developed. In New Zealand since 1926 the children's courts have had very broad powers, including aid to unmarried mothers which extends, when necessary, to helping them find employment. There is a federal child welfare service under the Education Department which makes investigations in connection with mothers' pensions and supervises placement of dependent children, as well as taking charge of work for the handicapped. Japan has had school physicians in all primary schools of cities of 5000 or more since 1896. Stringency of funds, however, has prevented much progress in reducing maternal mortality; and child labor is still a serious problem.

Problems of child welfare are closely related to almost all the major concerns of mankind. The improvement of social organization, the adjustment of class and race relationships, the efficiency of government and all its agencies, the stabilization of international relations, the need for greater scientific knowledge, are only a few of the social problems which have important implications for the welfare of children. To make the utmost use of all that science and a world at peace can offer is implied in any thorough program of child welfare.

NEVA R. DEARDORFF

CHILD HYGIENE. The term child hygiene is used to describe the consciously planned promotion of the health of children from the prenatal period through adolescence as well as of the mother's health during the prenatal period and the child's early infancy. The development of child hygiene has been a matter of slow evolution. It began with attempts to put an end to infanticide and the grossest cruelty. Efforts to save the child's soul followed, with very slight and often misguided attention to his body. Now the objectives of child health programs include not only the prevention and cure of disease but vigorous and healthful development for all children.

Infant mortality, even down to the nineteenth century, was startlingly high. A writer in a French medical journal of 1780 stated that at that time half of the children born in France

died before the end of their second year, and all available information indicates that this statement is an accurate picture of conditions then prevailing in most European countries. Wholesale wastage of child life was until comparatively recent times ordinarily accepted as an inescapable edict of Providence.

There is little evidence of any knowledge of child hygiene in early civilizations. The methods of the Spartans, who from approximately the eighth century B.C. exposed babies judged to be unfit and gave rigid physical training to children allowed to survive, were despite their crude severity and inadequacy the most effective known at that time and for centuries thereafter. In the second century A.D. Soranus of Ephesus, who might be called the first obstetrician and pediatrician, laid down in a medical book for mothers a number of sound principles of child hygiene. He emphasized the importance of breast feeding, gave directions as to frequency of nursing and warned against feeding at irregular intervals. Oribasius (325-403 A.D.) supplemented Soranus' teaching with instructions for the care of older children, commenting upon the need for regularity in meals, exercise, bathing, sleeping and other details of personal hygiene. Such teachings, however, received scant attention; in 1782 William Black of London in a historical sketch of medicine lamented the "carnage among the young of the human species" and the infrequency of any special attention to infantile diseases. "Up to this century," he said, "the management of these tender creatures in sickness was left to ignorant old nurses and rude quackery."

An Englishman, John Bunnell Davis (1780-1824), stands out most distinctly as the founder of modern child hygiene. In a small book, *A Cursory Inquiry into some of the Principal Causes of Mortality among Children, with a View to Assist in Ameliorating the State of the Rising Generation in Health, Morals and Happiness* (London 1817), he showed a real understanding of the causes of infant mortality and of the measures necessary to reduce it. He established the first public dispensary and organized a corps of home visitors, thus laying the foundation for modern systems of public health nursing for children.

Another important step was taken in France in the middle of the nineteenth century. In 1854 M. Morcl, as mayor of Villiers le Duc, had unobtrusively initiated a baby saving program which resulted in the reduction of the village

infant mortality from 300 to 200 per 1000 live births. This campaign lapsed but forty years later his son, who became mayor, revived it with an astonishingly thorough plan. This program included the reporting of all pregnancies, efforts to see that every mother nursed her baby for at least a year and provision of a wet nurse if she could not do so, weighing every baby once a fortnight and reporting the illness of every young child within twenty-four hours; it also provided the services of a physician at least once a week and a community herd to supply clean milk to nursing mothers and children. From 1893 to 1903 the infant mortality of Villiers le Duc is reported to have stood at zero.

In 1889 a very simple consultation center for mothers and children was established in New York by Dr. Henry Koplik. In 1890 a similar center was founded at Barcelona, Spain, by Dr. Francisco Vidal Solares, a Cuban physician; and in the same year Dr. A. Herrgott established at Nancy the *Oeuvre de la Maternité*, which had wide influence in other countries. School medical inspection, although of a very elementary sort, had its origin in Paris as early as 1834. The sharply declining birth rate of France gave impetus to all these movements for the conservation of child life.

Toward the end of the nineteenth century, under such leaders as M. Morel and Dr. Pierre Budin of France, Benjamin Broadbent of England and Dr. L. Emmett Holt and his associates in the United States, there developed a more scientific attitude to replace the crude evolution of hygiene technique through the trial and error method. This new attitude, which was especially evident in the handling of child health problems, had a highly stimulating effect on pediatric practise and on the enlistment of public support for child health measures.

During the first decade of the twentieth century much progress was made in infant welfare, particularly in England, Germany and the United States; New Zealand was in the vanguard in the popularization of public health programs for infants and children. During the war health work for children, as a conservation measure, developed rapidly, especially in the field of consultation centers for mothers and infants as well as for older children. England took a far reaching step at that time (1918) through the extension of grants in aid to private and public agencies for maternal, infant and child welfare work. Somewhat similar legislation

was adopted by the United States in 1921 through the passage of the Sheppard-Towner Act.

It was during this decade that attention was first concentrated upon scientific feeding and care of infants. To previous knowledge of the importance of breast feeding and of the necessity for scrupulous protection of milk and its scientific modification were added newer dietetic findings. These included such things as the value of vegetables in the early diets of children and the effects of a well regulated dietary for the mother during pregnancy. For growing children of all ages laboratory experiments in recent years have shown clearly the value of the so-called protective foods, such as milk, butter fats, citrus fruits, tomatoes and green vegetables, as well as whole cereals and other elements necessary for a well balanced diet.

Another subject of considerable research has been the effect of sunlight and of artificial irradiation on growing children, and their value in allowing the body to make the best use of certain growth foods, especially those essential to bone growth, not only through the direct action of sunlight upon the body but also through the vitamin value which has been stored up in foods. The use of ultraviolet light for therapeutic treatment of diseases, other than rickets and some forms of tuberculosis, is still in the experimental stage, and it has been found that neither sunlight nor artificial irradiation lessens the need for milk and certain foods which supply food calcium or for other essential food elements.

The control of communicable diseases constitutes still another field of research. The recent proof that diphtheria may be controlled as completely as smallpox through immunization has afforded an invaluable protection for children of preschool age, a period when diphtheria mortality has been highest. Immunization against typhoid fever is accepted as an essential protection where sanitation is inadequate, and immunization against scarlet fever gives hope of success. Thus emphasis in the control of communicable diseases has shifted from quarantine, which of course is always necessary, to active immunization wherever possible in dealing with the more serious diseases of childhood.

In the protection of motherhood convincing evidence was secured relating to the effects of education and health supervision of the mother during pregnancy, and of aseptic, skilful obstetrics, with a minimum of instrumental inter-

ference, in preventing deaths of both mother and infant. It soon became evident that there was a need for improvement in educational program methods and personnel in order to make effective for large numbers of children the knowledge and technique which had been acquired by research technicians and pediatricians. The activities of specialists in various fields were often unrelated or without coordination. In most countries medical supervision of school children had been extended rapidly without much attention to thoroughness of examination, follow up procedure or the educational use of findings. Until recently teaching of health subjects in the schools was often academic and sterile, without any vital relationship to the child's own social status and habits. Because of insufficient study and health supervision the preschool age was termed the "neglected age" of childhood.

Modern workers have recognized these obvious weaknesses, and the chief characteristics of a modern and progressive child health program are inclusiveness, thorough integration of various special health services, emphasis on prevention and a carefully planned educational program. The usual protective work of the health department in controlling communicable diseases, in sanitation and in safeguarding water and food supplies is supplemented by positive efforts to see that health examinations, immunization and advisory health services are available for children of all ages. The old abstract teaching of physiology and hygiene in the schools is being modernized by programs, devices and exhibits to stimulate children in building up wholesome daily habits. Health teaching is co-ordinated closely with such subjects as physical education, home economics, biology, civics, history and art.

As special services are introduced into a health program they must be closely correlated around common objectives, so that all activities may be parts of a well integrated whole. The need for an accurate judgment of comparative values and a nice balancing of program elements is illustrated by the problem of undernutrition. At the beginning of the twentieth century an alarmist view held that the prevalence of undernutrition was primarily if not exclusively an evidence of insufficient food, due to widespread poverty. It is now known that although poverty constitutes a menace to child health in many ways, malnutrition may be prevalent in the homes of the wealthy as well as among the poor, as a result of faulty selection of foods, insufficient rest, the

aftermath of localized or general infections or other causes. Thus the question of preventing undernutrition is seen to be as comprehensive as the whole range of child health effort. The modern school health program also illustrates the desirability of unified services and cooperation of personnel. For instance, the results of school medical examinations should aid the family physician or the clinic in the correction of defects, help public health nurses and parents to safeguard the child's health and to improve home conditions, and lay a foundation for the classroom teacher's guidance of the child into satisfactory health habits.

The newer discoveries in mental hygiene have given added emphasis to the knowledge that the effect of unwholesome surroundings, physical abnormalities and personal maladjustments are subtle but powerful and may crop up in unexpected ways. A well rounded health program, therefore, takes into account all of these personal and environmental factors, physical or mental. Physicians, especially pediatricians, and other public health workers now increasingly realize the need for cooperation.

Since the progress of medical knowledge has pointed the way to preventive health measures, authorities on child health now agree that emphasis is shifting from the mere protection from disease and correction of defects to the actual building up to the highest possible level of the child's health, vigor and general enjoyment of his physical and mental powers. This requires a working knowledge of the whole realm of healthful living on the part of both parents and children, as well as preventive supervision by physician, teacher and nurse. It presupposes that what is taught the individual must be practically related to his previous knowledge, experience and conditions of life. Hence a demand has arisen that the information intended to guide parents and children be simplified in order that by means of public health education it may be made common property. To popularize such information among parents and children and to carry on educational publicity in the field of health many lay organizations have been founded. The increased understanding of community health needs as a result of their work prepares the way for the government to assume further responsibility in health matters.

The machinery for putting child health programs into effect has varied widely in different countries, as have the objectives of these programs and the emphasis given to their constitu-

ent parts. Nevertheless there have been certain trends in the establishment of administrative machinery which are common to the child health movement throughout the world. These are exemplified in health legislation and the organization and work of bureaus of child hygiene and both public and private educational agencies.

Legislation affecting child health may be national, provincial, state or local. In addition to general public health legislation, which affects the health not only of mothers and children but of the whole population, there have been numerous laws passed dealing specifically with problems of maternal or child hygiene. These laws may be classed as regulatory, as creating governmental agencies or as providing for subsidies.

Regulatory legislation covers a wide range of subjects, including particularly the reporting of infant births and deaths, the training and qualifications of midwives and maternity nurses, compulsory prophylactic treatment of the eyes at birth to prevent *ophthalmia neonatorum*, reporting of any inflammatory condition of the eyes of the newborn as well as provisions regarding the sanitation of school buildings and the licensing, inspecting and regulating of maternity and children's homes and agencies for placing out children in private homes. It may also include the requirement of health examinations before the issuing of employment certificates to working children.

Legislation for creating governmental agencies usually provides for bureaus of child hygiene, either separately or as divisions of health departments, for purposes of general education in maternal and child health problems and for the supervision of agencies and workers in the field. As corollaries to such laws are the appropriations, usually annual, for the support of the bureaus. The administration of the regulatory laws is often left to separate bureaus. There are also allied laws establishing schools or institutions for the blind, the epileptic, cripples and other groups of children physically handicapped.

Governmental subsidies have been one of the newer methods of stimulating local activities in the field of maternal and child health. Such subsidies may be made with or without the proviso that they must be matched by local appropriations. In Germany, France, England, Italy, Russia, Hungary, Austria and Spain subsidies have been provided by law for mothers both before and after confinement.

Legislation prohibiting grossly injurious conditions of labor for women and children and measures providing mothers' pensions to maintain the child in the home should also be noted here as potential forces for safeguarding children from accident and disease.

Child hygiene bureaus have been established by law in some countries, with power to promote child health programs under either governmental or private auspices within their jurisdiction. In general, both national and provincial bureaus are concerned primarily with initiating, supervising and encouraging local work, while local bureaus are charged with the actual administration of community child health projects.

For several decades there have been, in most large countries, private organizations, either national or local, for the purpose of promoting the health education of the public, doing pioneer experimentation in fields not yet covered by official agencies and bringing effective support to the better type of governmental bureaus in securing appropriations and extending their work. National and district conferences on maternity and child health have been organized more frequently by private than by governmental agencies.

The most common forms of administrative and educational machinery for child health are regular health conferences for mothers, infants and older children, routine examinations of school children, public health nursing in the home, children's hospitals and, especially in European countries, convalescent homes, fresh air camps, preventoria, traveling health conferences and clinics, dental clinics and psychiatric or child guidance clinics for the elimination of personality maladjustments, the provision for a director of all health teaching in schools, exhibits for the information of the public or of professional groups, and institutes or special courses for giving up to date training in child health to pediatricians, teachers, nurses and parents.

To supplement these administrative and educational facilities a wide variety of devices for stimulating public interest has been used in various countries. These have ranged from Morel's attempt to stimulate better infant care in Villiers le Duc by promising to pay a small sum to each baby on its first birthday to the plan widely used in the United States of awarding stars, medals or honorary titles to school children for the observation of sound health habits or the correction of correctible defects or both.

The infant mortality rate of a country or

region is commonly used to judge the results of its child health work, not because it is a sufficiently comprehensive index but because it is the most sensitive readily available. The infant mortality rates of England and Wales (the earliest valid rates obtainable), while almost static from 1851 to 1899, dropped sharply from 163 infant deaths per 1000 live births in 1899 to 70 in 1926. The coincidence of this decline with the inauguration of child hygiene and general health measures is striking. Similar correlations between increased child hygiene activities and downward trends in the death rates of both infants and older children have been widely observed.

The general decline in child mortality which has taken place in most European countries and the United States since 1890 has been aided by improvements in economic conditions and public sanitary measures, particularly those relating to the control of milk and water supplies, as well as in general health supervision. Studies of child mortality in communities with effective child hygiene programs have shown lower death rates for children who were supervised than the average for unsupervised children of the same age. The reductions have been primarily in deaths from diarrhea, enteritis and the acute infections of childhood and to a smaller degree in deaths from the less acute respiratory diseases.

In the meantime there has been no general lowering of maternal deaths nor of neonatal infant deaths from such causes as congenital malformations or debility, premature birth or injuries at birth. A decrease in mortality from these causes has, however, been sometimes effected through the intensive effort of individual hospitals and health services, careful supervision of mothers during pregnancy, skilful aseptic deliveries and postpartum care of high quality.

The question has been raised whether the saving in infant life that has been brought about has not had a tendency to preserve the unfit; but the weight of evidence is decidedly to the contrary. It appears rather that in addition to reduced mortality another result of protective measures has been to save normal children from those diseases whose effects are likely to prove injurious in later years. But since child hygiene is no longer simply a matter of preventing disease and premature death, research workers are now faced with the task of devising satisfactory criteria for judging positive gains in the health of individual children.

COURTENAY DINWIDDIE

CHILD AND INFANT MORTALITY. The rate of child and infant mortality is an especially sensitive index of social and economic conditions. Infant mortality rates, especially, vary with such factors as economic status, family income, housing, mothers' employment and positive programs for the conservation of child life. Although the rate of child and infant mortality has in recent years steadily declined, it is still high in comparison with the mortality of adult years. Although child mortality and infant mortality may involve factors different for the two periods, the social cost of high infant and child mortality rates differs only quantitatively and similar means are effective in the reduction of both.

The general mortality rate is measured by relating deaths to the average population exposed to the risk of dying. For the age group under five, accordingly, the mortality rate is found by dividing the deaths under five by the estimated population under five in the same area for the same period. Since population figures are available only for census years, it is customary to use in the denominator estimates of population calculated to the midpoint of the year to which the deaths relate. There are several sources of error in computing such rates. Since the numerator of the rate fraction is based on deaths which are registered as having occurred during the period (usually the calendar year), errors due to omissions of registration may affect the rate. Nevertheless, in countries where the custom of registration is general, where burial in cemeteries is the rule and where a permit issued only after registration is required for burial, such omissions are not numerous enough to affect the figures materially. There are, however, specific sources of error for child and infant mortality rates. Estimates of population for ages under five based upon census enumerations may depart appreciably from the true figures, since the number of live births and the number of children who die vary considerably from year to year. In calculations of infant death rates this source of error is so important that such rates are commonly calculated by dividing the deaths under one year by the number of live births, instead of by the estimated infant population. This comparison with births, however, requires accurate birth statistics if the basis is to be correct. In general, birth registration is less complete than the registration of deaths.

Statistics of births for the United States birth

registration area have been published only since 1915, when the area included ten states and the District of Columbia and covered about 31 per cent of the population. Estimates of omissions in birth registration for 1919, when it was possible to utilize the census as a basis for comparison, indicate an average percentage of omission of about 8.0 for the birth registration area. In other countries the percentage of omissions is in most cases low because registration of births has been in effect for much longer periods, as for example in England since 1837 (voluntary) and 1872 (compulsory), and greater stress is laid upon complete registration. In comparing infant mortality rates between countries and at different periods, allowance must be made for the effect of differences in the completeness of registration.

The rate of mortality in childhood shows a steep downward curve. It commences at a high figure at birth, falls very rapidly through the first month and the first year of life and continues to fall in succeeding years, though less and less rapidly, until the lowest death rate is reached at about twelve or thirteen years, after which the rate rises steadily with increasing age. Not until advanced old age does the mortality equal that of the first year of life. In the United States in 1925 the mortality rate under five years was 19.7 per 1000 for the death registration states of 1920. Under one year the mortality was 75.3, while for the years from one through four the rate averaged only 6.3.

For the five-year period five through nine the rate drops about one half, while the years ten through fourteen are the healthiest of the whole life span, with a mortality of about 2 per 1000. Because the excessive mortality of early childhood decreases rapidly in succeeding years, it is the earlier years, particularly those under five, to which students of vital statistics have given most attention.

Table 1 presents mortality rates by sex and age for thirteen of the principal countries during the period 1901-10 or for the nearest corresponding period. It indicates certain striking differences, for example, between India with infant mortality rates 289.98 and 284.60 for male and female infants respectively and rates of 36 and 33.7 for the four-year olds, and Norway with infant mortality rates of 81.45 and 66.79 and rates for four-year olds of 5.16 and 4.91 respectively.

Dr. Louis I. Dublin, one of the few authorities on vital statistics who have made an intensive study of child mortality, has pointed out some interesting facts with regard to its causes. Diseases peculiar to early infancy, such as congenital debility and premature birth, are not a factor after the first year. During the second year nutritional diseases are the chief cause of death, with respiratory diseases coming next; epidemic diseases are more serious than in the first year, and fatal accidents, including burns, increase in number. In the third year the epidemic diseases, diphtheria, whooping

cough, measles and scarlet fever, replace nutritional diseases as the prime cause and are responsible for a quarter of the deaths; respiratory diseases follow in importance; and there are more accidents.

During the fourth year epidemic diseases account for about a third of the total mortality, respiratory and digestive diseases decrease and vehicular accidents take a larger toll. In the fifth year there is a slight increase in typhoid, and practically the first onset of appendicitis appears. Organic heart disease and nephritis, possibly from the sequelae of epidemic diseases, become factors.

TABLE II

CAUSES OF DEATH OF CHILDREN 1 TO 4 YEARS OF AGE, INCLUSIVE, FOR 1925, IN UNITED STATES DEATH REGISTRATION STATES OF 1920

During the five to nine-year period, heart disease and typhoid fever increase; bronchopneumonia is more prevalent than lobar; and whereas tuberculosis among younger children is largely of the meningitis type, during this period the pulmonary type leads. There are more falls and drownings, and automobile accidents in ever mounting number take the heaviest toll at this age. Hitherto diphtheria has been an outstanding cause of death in the five to nine-year period, but preventive work is rapidly reducing its frequency.

In the later years of childhood the causes of mortality increase, thus approximating the situation in adult life. In the healthiest years, ten through fourteen, tuberculosis chiefly of the pulmonary type is the greatest danger; the typhoid and appendicitis rates rise; and pneumonia is then at a minimum. Acute infections are less serious than organic heart disease, articular rheumatism and diabetes. In addition to drowning and automobile accidents, there are more fatalities due to the use of firearms and the like.

The separate recording of mortality of children from one to five years has been responsible in part for a recognition of the seriousness for this period of epidemic and communicable diseases, not only in their primary degree as causes of death but in the causal relation between them and a series of pathological conditions appearing in later life as a result of organic and hangover infections.

Recent medical progress gives promise of virtual control of the epidemic children's diseases, with a great reduction in the death rate from these diseases and their sequelae. In the case of diphtheria and scarlet fever it is possible to determine by simple tests whether or not a person is susceptible to the disease, and to produce effective immunity. Treatment by antitoxin, if promptly applied, greatly reduces the danger of death in both diseases. Increasing success in combating tuberculosis has vitally affected the mortality rate in the five to nine-year period, in which it has been the chief cause of death. Progress in wiping out the diseases which are especially hazardous to children depends in part on increased medical knowledge, general health education, particularly that of parents, and public health measures, which in reducing the general death rate have a beneficial effect in lowering child mortality, not only directly but through lessened danger of infection. One minor but serious cause of child mortality, namely death from accident, has steadily increased to continually greater hazards despite extensive efforts for safety education. School health examinations, when accompanied by efficient follow up work, help to safeguard children of school age and to minimize the spread of infections to other children. Recently health campaigns have canvassed the needs of the preschool child for the purpose of adequate protection. A comparison of the average rate of mortality in the United States death registration area as shown in Table II with the rates for the period 1901-10 shown in Table I exhibits as marked an improvement in mortality for these years as for the first year.

Infant mortality has been much more widely studied than child mortality in general because of its exceedingly high rate in all countries relative to the mortality rate of adult life and later childhood, because of its association with questions of maternity welfare and because statistically it presents certain unique problems, being subject to sources of error which make necessary the use of a different basis of reckon-

ing. More complete data are available with regard to the causative factors of infant mortality than for child mortality in general.

The preponderating causes of mortality during the first year, as indicated by Table III, are conditions present at birth itself or those resulting from injuries at birth; next in order of importance are the gastric and intestinal disorders related to difficulties in feeding, the respiratory diseases and the communicable diseases. A comparison of the data for 1915 and for 1926 shows some significant shifts in cause.

TABLE III
INFANT MORTALITY BY CAUSES OF DEATH, 1915 AND
1926, IN UNITED STATES BIRTH REGISTRATION AREA OF 1915 *

CAUSE OF DEATH	1915	1926
All causes	99.6	74.7

Source: Compiled from United States, Bureau of the Census, *Birth, Stillbirth, and Infant Mortality Statistics for 1915 and 1926* (Washington 1917 and 1929).

In addition to the general reduction in rate from 99.6 to 74.7 there is a three fifths diminution in the deaths from gastric and intestinal causes, involving a shift from second to third place as a causative factor. Another important reduction is in deaths from congenital debility, under the grouping of diseases of early infancy. Congenital debility undoubtedly includes many deaths really due to feeding troubles. The combination of reduction in this group with that in the gastro-intestinal group indicates that feeding troubles are not only one of the chief

causes of infant mortality but one of the most preventable, since their origin is in lack of cleanliness and in negligence or in ignorance of the proper methods of infant feeding. This conclusion is borne out by the fact, not indicated in the table, that such deaths are far more prevalent in the summer months, while deaths from respiratory diseases occur most frequently, as might be expected, during the winter months. Congenital debility, properly so classified, has as a rule been one of the causes least responsive to efforts for infant welfare. Syphilis and alcoholism in the mother or her own constitutional defects, and injuries to the foetus before birth are among its chief causes. Prenatal care for the mother offers the best possibility of lessening the incidence of the so-called "wasting diseases." The rates from injuries at birth increased between the comparative dates by nearly one third. This is especially interesting when considered in connection with the high maternal mortality rate in the United States.

A study has been made by the United States Children's Bureau of the factors affecting infant mortality in eight cities in selected years between 1911 and 1915. The findings of this study offer some of the most detailed evidence available as to the cause of infant mortality. In considering the rates emphasis is to be placed upon the relative rates of mortality among the different groups rather than upon the absolute figures.

The study shows a correlation between the health of the mothers and the circumstances and types of births and the rate of mortality of the children. Among infants whose mothers died during the first year after confinement the rate was 450, or four times that (109.2) among infants whose mothers survived, probably a result partly of weaker constitutions and partly of the necessity for artificial feeding or foster care. Infants whose mothers were or had been tubercular had a mortality of 271, or two and one half times the rate (102) among other infants, again possibly due to a generally weaker inheritance, to the contraction of tuberculosis by contact with the mother or to the necessity for artificial feeding because of the weakened condition or death of the mother. Male infants had a rate about one fourth higher than that of female infants, an excess which appears not only in causes peculiar to early infancy, where the greater size of the male infant may be a factor, but also in practically every cause of death, indicating a generally lower vi-

tality for male infants. The mortality of twins and triplets was 363, or three and one half times that of single born infants. Prematurely born infants were subject to a very heavy death rate, more than six times as high as among those born at term. An unusually large proportion of twins and triplets were premature. Infants whose mothers were delivered by means of instruments had a mortality of 120.3, considerably higher than 102.1, the rate for other infants.

The mortality among artificially fed infants, averaged month by month during the first year, was from three to four times as high as among those who were breast fed. The excess of deaths was especially noticeable during the first six or seven months, gradually falling toward the end of the year. Although in many cases the artificially fed infants were handicapped by inheritance of weak constitutions, as in the case of the prematurely born, the twins and triplets and those whose mothers died, yet the excess mortality among the artificially fed was found to be equally great among infants not affected by these factors, among the single full term infants whose mothers survived the year. The analysis indicated that artificial feeding was directly correlated with higher mortality and that, during the first six months of life, the earlier the artificial feeding began the higher was the mortality among the artificially fed infants.

The factor of the mother's age in infant mortality rates, as ascertained by this study, is shown by the following figures:

AGE OF MOTHER	RATE
Under 18	160.3
18-19	128.9
20-24	109.5
25-29	101.4
30-34	104.7
35-39	126.5
40-44	131.3
Over 45	250.0 ¹

Based on less than 100 cases.

It appeared that the infants of mothers between 25 and 30 have the best chances of survival and that, contrary to popular opinion, the infants born to mothers from 35 to 40 years of age have a better chance than those of mothers of 18 and 19 years.

Order of birth also was found to affect the child's chance of life. First births had a slightly higher mortality rate than second (104.7 as

compared with 95.7); after the second birth the rate of mortality increased slowly for the third and fourth, and then more rapidly to 146.8 for the ninth, and 181.5 for the tenth and later births.

The spacing of births was revealed as a decidedly important factor. The mortality among children who followed preceding children after an interval of one year was 146.7 as compared with 98.6, 86.5 and 84.9 among children for whom the interval was two, three and four or more years. Artificial feeding, with the concomitant danger to survival, was markedly more prevalent among children born within one year of the preceding birth. The interval before the succeeding pregnancy also affected the infant's chances for survival, and over two and a half times as many infants whose mothers became pregnant again within the year died, as compared with the average for infants during the same months of life.

A marked correlation was found between the infant mortality rate and the economic status of the family, as shown by the father's earnings (Table IV) and by the income from the father's earnings per capita for the members of the family. The lower the father's earnings and the lower the per capita income the higher were the infant mortality rates. The correlation was particularly marked between low earnings of the father and death from gastro-intestinal causes and epidemic and communicable diseases. Although a smaller proportion of the infants of the low earnings groups was artificially fed the mortality rates of those who were artificially fed were unusually high, suggesting that this type of feeding in the low income families was fraught with increased hazards of infection or serious digestive disturbances.

The influence of the mother's employment upon infant mortality is marked. Employment away from home appeared, in the Children's Bureau studies, to be associated with heavy infant mortality rates. Infants whose mothers were employed away from home during pregnancy had a mortality rate of 176.1 as compared with 114.6 for those whose mothers were employed at home, and with 98.0 for those whose mothers were not employed. Employment away from home during the child's first year of life was associated with a mortality two and one half times as high as that among infants whose mothers were not employed. This group overlaps in large part with groups in which the fathers had low earnings. Both low family in-

come and employment of the mother away from home, which often necessitates artificial feeding, were contributing causes to the high infant mortality rate.

Race and nationality also are important factors in the survival of the infant. Table v shows the infant mortality rate in relation to the color and country of birth of the mother. These

TABLE V

INFANT MORTALITY RATES, BY COLOR AND BY COUNTRY OF BIRTH OF MOTHER, IN UNITED STATES BIRTH REGISTRATION AREA, 1925

COLOR AND COUNTRY OF BIRTH OF MOTHER	INFANT MORTALITY RATE
Total	71.7
White	68.3
Native born	64.9
Foreign born	76.8
Austria, Hungary	82.8
Canada	80.8
Denmark, Sweden, Norway	55.6
England, Scotland, Wales	61.2
Ireland	73.9
Germany	62.0
Italy	69.9
Poland	93.6
Russia	55.4
Other foreign countries	94.6
Negro	112.0
Other colored	95.6

figures would have been more instructive if each of the groups were further analyzed as to earnings of father and employment of mother.

It will be seen that infants of white mothers have a mortality only two thirds as high as

have those of colored mothers. While infants of native mothers stand a better chance than those of foreign born, infants with Russian, Scandinavian, English or German mothers have a lower mortality, in the order named, than infants of native mothers. An analysis by race and nationality in the groups studied by the Children's Bureau indicated that differences in mortality rates by nationality were not due merely to differences in economic status or in types of feeding; in many cases the effects of differences in economic status and in prevalence of artificial feeding tended to offset each other. The Jewish group had a mortality rate strikingly lower than all other groups, including the native born; and this held good even in the presence of many other complicating factors usually contributing to a high death rate.

The mortality rates are slightly higher in urban areas than in rural districts, the rates for the birth registration area in 1926 being 74.2 for cities and 72.4 for rural districts.

Illegitimacy is another circumstance making for a very high infant mortality rate in all countries. Statistics for England and Wales (1920) show the effects of the handicaps associated with illegitimacy. In that year infant mortality rates for the illegitimates were 171.2 (male) and 140.4 (female), as compared with rates for legitimate children of 86.0 and 65.8 for males and females respectively. Here we have again as possible contributory factors the high percentage among illegitimate infants of artificial feeding and institutional or foster care; a low income or no income from the father; the likelihood of the mother's employment away

The other figures are taken from the statistical yearbooks of Australia, Austria, Belgium, Bulgaria, Canada, Denmark, Finland, Hungary, Italy, Japan, New Zealand, Norway, Sweden and Switzerland, annual reports of the Registrar General of England and Wales, *Bulletin de la statistique générale de la France*, vols. ix, x and xii, *Statistik des deutschen Reichs*, vols. xiv, xv and xvi.

from home; and the comparatively low age of mothers.

The listing of various factors resulting in high or low death rates does not in itself give an explanation of the basic causes to which infant mortality is due. Many factors are present in each case; hence for any group as a whole the various influences overlap and are intricately related and interdependent. Thus while infant mortality varies with age of mothers, a higher infant mortality being associated with mothers at either extreme of the age group, complicating data of many kinds must be considered: racial factors, number of first births, intervals between births, numbers of premature

and of plural births, health of mothers, extent of artificial feeding, economic status. Elaborate and careful calculations, therefore, are required in order to discover what element in the situation is decisive in any given group.

Concomitant with world wide advances in public health measures, infant mortality rates have been very greatly reduced during the past forty or fifty years. Comparison of the figures given in Table VI for the period between 1884 and 1893 with those for 1915 shows a remarkable decrease in all countries represented. The decrease has continued in the post-war period with only minor fluctuations.

ROBERT M. WOODBURY

CHILD PSYCHOLOGY. If this term were broadly construed to comprehend all knowledge and doctrine pertaining to the mental life of children the history of child psychology would parallel that of human culture. Even before man could formally write out his reflections on child nature he entertained notions and attitudes which constituted a primitive form of child psychology—a mixture of fact, inference, ignorance, philosophy, mores and sentiment. Modern child psychology has taken shape only within recent decades, and even today it has by no means escaped all of the imperfections of primitive psychologizing. With the employment of scientific method, however, errors are being steadily reduced and the manifold problems of child development are approached in a new spirit of rationalism.

The present widespread investigation of the child mind is itself a significant social symptom. It represents an increasing disposition to attribute even the phenomena of human behavior to natural rather than to miraculous causes. This rationalistic temper is dissolving the rigidities of dogmatic theology and of dogmatic ethics which so powerfully influenced the psychological attitude toward children from the time of St. Augustine to that of Jonathan Edwards—and of Charles Dickens. Pre-scientific interpretations of the mind of the child imputed to him a will separate from his general psychology, an almost demoniacal self-will born with his original sin and in no sense the natural product of individual development.

The newer interpretations of the child emphasize the unity of personality and are based upon biological concepts of growth and of organism. The child is regarded as part of the order of nature as well as of society, obedient in his behavior to laws ascertainable by methods of orderly observation, measurement and experimentation. Child psychology, even in its present undeveloped stage, has already opened up large areas of predictability and control in the domain of human behavior.

In its early modern development child psychology was closely identified with the history of elementary education, which had itself been profoundly affected by the industrial revolution. Comenius (1592–1670) in his *School of Infancy* (1633) and *Orbis pictus* (1658) and Locke (1632–1704) in his *Some Thoughts Concerning Education* (1693) foreshadowed the psychological approach upon problems of pedagogy which were elaborately treated by Rousseau, Pestalozzi,

Froebel and Herbart. Although these educational reformers were in no sense technical psychologists their writings did much to humanize the care and discipline of children and to psychologize the educational process. They greatly advanced the genetic or developmental point of view, a remarkable achievement for a pre-Darwinian and almost a pre-biological age. Froebel drew upon horticulture and crystallography for some of his insights; Pestalozzi kept a diary of his newborn son; Herbart developed a semi-mechanistic associational psychology. The present day interest in the psychology of the preschool child was anticipated in three suggestively diverse directions—by Dietrich Tiedemann, a philosopher, in *Untersuchungen über den Menschen* (1777–78); by Robert Owen, a social reformer; by Madame Necker de Saussure, feminist, in *L'éducation progressive* (1828–32); and by Susannah Wesley (1669–1742), also something of a feminist, whose letters to her famous son John present an amazing picture of parental doctrine in the eighteenth century. Owen wrote glowingly on the perfectibility of the human infant and founded the first nursery school in the British Isles (New Lanark, 1800) as well as the first in the United States (New Harmony, 1826). The child study movements of the eighties and the nineties in the United States illustrated that mirroring of social settings and social strivings which has frequently characterized child psychology. There is a similar reflection in the nursery school movement both in England and in the United States. The relationship can also be observed in contemporary Russia, where it is asserted that the complex science of “pedology,” first brought forth in America by G. Stanley Hall, finds a larger realization under favorable social conditions. The reciprocal relations between child psychology and ideologies constitute a persisting critical problem for the social sciences.

No one person can be counted the founder of child psychology; its scientific sources are international. Wilhelm Preyer, a physiologist, wrote in 1882 *Die Seele des Kindes* (5th ed. Leipzig 1900; tr. by H. W. Brown, 2 vols., New York 1888–89), a book intrinsically and historically of basic importance. G. Stanley Hall has claim to special mention because the child study movement of the late nineteenth century was predominantly an American movement of which he was the leader. He attempted, moreover, in his voluminous writings to set forth the ontogenesis and phylogenesis of the mind with the wide

purview of Darwin. In his volumes on *Adolescence* (2 vols., New York 1904) and in numerous other penetrating and suggestive studies he made substantial and germinal contributions to the study of mental development. Among leaders and early contributors in other countries may be listed Bernard Pérez and J. G. Compayré in France, Paola Lombroso in Italy, James Sully in England and Ivan Sikorsky in Russia.

In its early period child psychology was largely descriptive and utilized simple, informal methods of observation. With the growth of technique in related fields of study, controlled and quantitative methods have come increasingly into use. The scientific literature has expanded with striking rapidity. Three trends are distinguishable in the development of recent investigations: the experimental, the psychometric and the psychobiological.

Experimental psychology, the first laboratory for which was founded by Wundt in 1879, has been chiefly concerned with the adult mind and has been bound up with introspection. But with the new realization that the understanding of this adult mind depends upon a genetic analysis of its early development the methods of the experimental laboratory have been carried to the lowest age levels. The techniques of physiology and of animal psychology are being adapted to the study of learning and conditioning in infancy. Both behaviorism, which is closely allied to physiology, and Gestalt psychology have an experimental interest in child behavior.

The nursery school movement in America has promoted child research as well as preschool and parental education. Such schools are functioning as university laboratories for the conduct of controlled observation. This observation is becoming more and more experimental in centers like those in Iowa, Minnesota and California in the United States, and in Geneva and Moscow abroad. Controlled studies of early social behavior have begun to figure prominently. The research clinic at Yale has made experimental use of the cinema for the normative study of developmental changes in the behavior patterns of the infant.

Psychometry, or the measurement of individual differences, is associated with the names of Galton, Cattell, Thorndike and Binet. The Binet measuring scale of intelligence has had a prodigious development in America and has with a host of related mental and educational tests created volumes of data for the study of the individual child and the group. Despite its errors

and shortcomings the mental test movement has created a new technology of great social import. Psychometry has been most successful in the gradation and classification of differences of intellectual capacity, but it has not dealt effectively with the important factors of emotion, motivation and personality. Intelligence norms have had their widest application in the study of children of school age, but they are being rapidly applied to preschool children. Procedures for the developmental diagnosis of infants are being defined.

Individual or clinical child psychology may be regarded as a special development in the field of mental measurement. It represents an effort to use the techniques of psychology to appraise the abilities and developmental potentialities of both normal and deviating individuals and is becoming a supplement to clinical psychiatry in the fields of child guidance and of mental hygiene.

Psychobiology is a compound which reflects the current trend toward a monistic or organismic outlook upon scientific problems. In the sweep of this trend child psychology tends to lose a sharply defined identity and to merge with the investigations of the fundamental sciences. The traditional concept of a self-subsisting mind accommodates itself to concepts which integrate "psycho" and "soma"—concepts like function, stimulus and response, behavior, emergence, Gestalt, gradient, growth. Hence it is that the scope and content of child psychology are being profoundly affected by a wide ramification into the subsoil of psychobiology. The term "child development" has become a rival if not a substitute for "child psychology." It is a protean but useful term and surely symptomatic of the current trend of science.

The problems of child development involve such varied scientific fields as biochemistry, developmental anatomy, nutrition, anthropometry, anthropology, psychiatry, pediatrics and genetic, experimental, comparative and clinical psychology. Child development is fundamentally a branch of human biology—a focal field for psychobiological and medical knowledge converging upon the central problem of early human growth. This is of course a widely inclusive field of inquiry, but it is a legitimate one because the phenomena of growth are subject to general and unifying laws which can be formulated only by coordinated contributions from several scientific domains. Growth is itself a unifying concept which removes undue distinctions between mind and body, between

heredity and environment, between health and disease and also between separate scientific disciplines.

This psychobiological concept of growth has important consequences for social welfare. It extends the scope of child psychology beyond traditional and academic limits and greatly augments the possibilities of safeguarding individual development from birth. In its special applied phases child psychology has become a distinctive feature of modern social organization, for it is being deliberately used as a scientific tool in the rational solution of age old problems of infant training, childhood education, the prevention and control of delinquency, the foster placement of dependents, the guidance of parents, the regulation of child adoption, the diagnosis of the defective and deviate, the management of the problem child, the care of the handicapped and maladjusted and the discovery and direction of superior abilities. Great and increasing numbers of children are now psychologically examined each year in public schools, in child guidance clinics, in institutions for the care of children and in child research centers. Although the available "psychotechnology" is imperfect and incomplete it is being used on an impressive and significant scale.

With the progress of psychobiological science this technology will steadily improve and the early span of human growth will come more fully under social control. Such control has been well established both in principle and in fact by the protection of the physical welfare of the newborn infant. But this is only the beginning of a policy of health supervision which must come to embrace mental as well as bodily welfare and to pay conservation heed to the preschool years of mental life. From the standpoint of developmental psychology the infant has a mind and a personality subject to the laws of growth. The scientific understanding of these psychobiological laws will lead increasingly to a constructive and preventive supervision of human infancy.

The protection of the infant's health widens to include his mental hygiene. The pressure of the great problems of mental defect and instability, of crime and malbehavior, demands a psychological science of childhood which in close association with the medical sciences can undertake a more conscious and systematic form of developmental supervision. The promotion of optimum growth, mental as well as physical, thus becomes a concept of public health and of

social control justified by advancing scientific knowledge.

The more unconscious and subtle effects of child psychology are perhaps more basic for social organization than the obviously humanitarian. The human infant by reason of his unique position in this organization is a focus surcharged with social issues and social implications. Although he is a biological fragment of nature he is also meshed in a web of human relationships. The interaction between his organic make up and these social influences is the crucial problem of child psychology or of child development. For this reason the system of child psychology which any culture achieves is an index of that culture. And conversely the scientific study of the process of mental growth in infant and child becomes a touchstone for the deeper comprehension of the process of social organization itself. Accordingly child psychology belongs at once to the natural and to the social sciences.

ARNOLD GESELL

CHILD GUIDANCE. This term has acquired a specific connotation as applying to the branch of the mental hygiene movement which is concerned with the personality and conduct disorders of childhood and which takes account of the complex interactions between the child and his environment and seeks to help him gain a workable orientation to his world. Child guidance offers a method for the scientific study and treatment of children who through their attitudes and behavior in the home, the school or the community exhibit difficulty in achieving a satisfactory adjustment to the demands of everyday life.

There are many manifestations of personal maladjustment in children. In younger children especially these are for the most part certain unhealthy habits, such as thumb sucking, nail biting, enuresis, masturbation, eccentric bodily movements, food whims and so forth. Maladjustments may appear in undesirable personality traits—oversensitiveness, obstinacy, tendency moods, seclusiveness, constant quarreling, laziness, lack of interest or ambition, exaggerated timidity, restlessness or general nervousness. Other manifestations may take the form of anti social tendencies such as lying, stealing, truancy, destructiveness, temper tantrums, suspiciousness, rebellion against authority, unhealthy sex interests or practises and the like. Occasionally it is found that problem children suffer from defi-

nite mental disorders. While the child guidance clinic sometimes deals with such cases, as well as with those of feeble-minded and defective children, its work is properly only with children capable of a more or less normal adjustment.

Although the behavior problems of childhood and youth have long challenged the resourcefulness of child protective agencies, early efforts to deal with these problems lacked scientific direction. The child guidance movement, based on scientific principles of child study and adjustment, reaches back in its origins to the founding of the National Committee for Mental Hygiene in 1909; and its growth is contemporaneous with the development of interest in mental hygiene which followed.

Since the founding of the National Committee more and more attention has been devoted to the mentally ill. Not only has psychiatric treatment for maladjusted adults gained widespread support but there has been a shift of emphasis in both research and practice to the earliest years of life. This change may be traced to the growing acceptance of the validity of the genetic and dynamic concepts in psychology, which received its strongest impetus from the contributions of Sigmund Freud. Careful study of the developmental processes in the maladjusted adult furnished increasing proof that the roots of his difficulties lay in early infancy and childhood. A realization of the decisive character of these early years when attitudes are acquired which will affect the individual in later life opened the way for the application of the findings of psychiatry to the needs of the maladjusted child.

The first practical demonstration of a coordinated effort for child guidance was made by Dr. William Healy and his associates, who established in 1909 a juvenile psychopathic institute in connection with the juvenile court of Chicago. Dr. Healy's work in Chicago and later in Boston furnished much of the stimulus and justification for the present day child guidance movement. As early as 1896 a psychological clinic for children had been founded in Philadelphia, and although for a time it had few imitators, in 1912 the movement for organizing psychological clinics got under way and progressed so rapidly that by 1914 there were more than a hundred in the United States, functioning in connection with medical schools, hospitals for nervous diseases, state institutions, schools and courts. Many clinics which at first emphasized only mental testing gradually took over and applied to the study of the child the findings of

psychiatry as these were developed. But the first well organized effort to promote child guidance clinics dates from 1921, when the Commonwealth Fund, as part of its program for the prevention of delinquency, inaugurated a five-year plan for the establishment of demonstration clinics in a number of cities throughout the country, the training of personnel and the provision of visiting teacher service in certain public schools. In 1927 there were, according to the *Directory of Psychiatric Clinics for Children in the United States* published by the Commonwealth Fund, nearly 500 clinics distributed through a majority of the states. In these clinics, which provided regular service for the study and treatment of juvenile behavior problems, over 40,000 children were treated during the year.

As every problem in child guidance is a problem of the "setting" or "situation" of the individual child it can be dealt with adequately only by taking into account all the relevant elements. It is of little remedial value to label a child thief, truant or coward if he steals, runs away from school or is easily intimidated, for behind these simple categories lurks a complexity of phenomena which can be understood only after a thorough study of the individual child and of the social and psychological setting of which he is part. Hence in actual practice child guidance is a question of team work, requiring the service of physician, psychiatrist, psychologist and social case worker.

Problem children are brought to the clinic by parents, teachers, probation officers, church workers and various social agencies. In each case the data obtainable from a thorough investigation are first secured, after which the child is given a careful medical examination, a detailed developmental, psychological and educational survey and an intensive psychiatric test. In its work with problem children the clinic utilizes all available scientific techniques and aims to furnish continuous, constructive treatment until the needed adjustment is achieved. In this process of adjustment, which often involves the remaking of the environment, the social worker is of key importance. One of the services most frequently required is that of obtaining vocational guidance for the older child.

In Europe there is little of the continuing treatment and clinical supervision of non-institutionalized problem children which has become established in the United States. In Great Britain the 1923 Home Office report recommended the establishment of observation homes

for psychological treatment in connection with the juvenile courts. The Tavistock Square Clinic in London now renders psychiatric services when called upon by the court. In Berlin nerve specialists connected with the juvenile courts make thorough examinations at the request of the judges, and the Jugendamt gives probationary supervision. In Austria there are psychiatric clinics attached to the juvenile courts. These courts have jurisdiction not only over delinquents but over dependent and neglected children as well. The Austrian school system keeps a record of the child's health and development, his habits, emotional reactions and, later, vocational preferences. Although these records are kept throughout the entire school course they are based only on the statements of school physicians and teachers and are used merely to supply data for vocational guidance. The central Office of Vocational Guidance in Vienna has a psychotechnician as liaison officer with Professor Bühler's Institute of Psychology, to which maladjusted children can be referred. Finally, the public *Hilfschulen*, or special schools, make provision for problem children. Russia has begun to establish a nation wide mental hygiene service with clinical facilities available to both children and adults.

In South America, also, there are beginnings of a child guidance movement. Colombia has recently instituted the requirement that all delinquent children be given a medical and psychological examination by a doctor who acts as adviser to the juvenile court judge. In Brazil and in Argentina recent legislation provides for the assistance of doctor-psychologists in connection with the juvenile courts.

The therapeutic and educative influence of the child guidance movement usually extends beyond the individual child to the parent, the school and even the agents of law enforcement. Child guidance is contributing much to the content and method of the educational process and is making itself felt in a better understanding of personality and conduct values in family life. The movement aims also to extend its influence to the playground, the workshop and the community itself, with a view to eliminating the obstacles to healthy development. In its broader educational aspects the child guidance clinic has come to be a community enterprise, concerned not only with the maladjusted child and the individuals immediately surrounding him but with the wider application of principles of mental hygiene by various social groups. In

some cases interest in child guidance has been directly responsible for new legislation and for the adoption of new standards of social practice. As a part of the larger mental hygiene movement child guidance has deeply affected the general field of social work, and the curricula of the various schools of social work are giving more and more attention to personality problems, both normal and pathological. A similar influence is becoming evident in the rapidly growing parent-teacher movement and in the popular interest in child study.

It is impossible to estimate how much individual and social maladjustment and suffering are being prevented by clinical work in child guidance. The aim of the child guidance movement is to make available to all children the mental hygiene principles and technique which have come to light as a result of the clinical work with maladjusted children. If every child upon entering school could have the benefit of such a thoroughgoing personality study as is at present available for those children who have already become maladjusted, much of the later work of reconstruction and rehabilitation could be avoided. With the broadening of its field to include a greater emphasis on educational and preventive work the child guidance movement is beginning to be not merely a service for maladjusted children but, as its name in the larger sense implies, a means of guiding all children to a stable life adjustment on the basis of the fullest utilization of their powers.

BERNARD GLUECK

CHILD MARRIAGE. *General.* Child marriage, in its narrower sense, means prepubertal marriage, although it is used also with reference to early marriages in complex societies where economic rather than sexual difficulties are involved. In any discussion of child marriage it is necessary to distinguish three aspects: betrothal, sex relations and the establishment of a home as an independent economic and social unit. In our own civilization these three aspects of marriage form an intimately associated complex, and we have come unconsciously to regard them as essential features of child marriage. Consideration of the subject has therefore been confused. Thus regions where the custom of child betrothal is prevalent are often regarded as areas of child marriage, although the betrothal is often an economic interfamilial contract having nothing to do with prepubertal sex relations or the establishment of an independent home. Again,

the aspect of prepubertal sex relations may be emphasized and child marriage condemned because of its deleterious physical effects. But while prepubertal sex relations and the institution of child marriage are found together, in many cultures they are not at all connected. Institutionalized infant marriage is often accompanied by strict observance of childhood chastity. Indeed, physical consequences of prepubertal intercourse must be studied quite apart from child marriage, for the institutionalization of premarital sex relations among children is very much more common than that of prepubertal marriage. In regions of central Africa where marriage does not take place until after adolescence, sex play is encouraged among children and no notice is taken of a girl's relations even with older men until she is adolescent. While the third aspect of child marriage, the establishment of an economically and socially independent home, is generally stressed in discussions of child marriage in America and western Europe, the problem is as a matter of fact usually non-existent. Since the economic unit of most societies is larger than our isolated family group (the "house group" includes a number of what we call "families," grouped by relationship bonds traced through the women or the men) the economic position of a couple as part of a larger unit is much the same after marriage as it was before. To emphasize in a study of such societies the economic reasons for which child marriage is condemned in our own civilization is to distort the problem.

The only sexually important feature of child marriage is of course that of prepubertal sex relations, which may consist of either sex play of pre-adolescent age mates or intercourse of mature men with girl children. Either of these may be institutionalized in connection with or apart from child marriage and neither is an essential concomitant of it. The first has been most fully described by Malinowski in his study of the Trobriands of northwestern Melanesia (*The Sexual Life of Savages*, ch. iii), among whom dalliance, beginning almost as soon as babies start to play together, is encouraged by the elders. It may well be doubted, however, whether this fundamentally affects the sex cycle of either girl or boy; neither here nor in the regions of central Africa (Johnston, Harry H., *British Central Africa*, p. 408, note i), where the same custom prevails, is there any reliable information as to the age of potency in boys. The case is different with intercourse between

girl children and mature men, a practise which is not frequently found in the New World but recurs in almost every great area of the Old. It may, as among the Arawa of southern New Britain, be associated with marriage; or among many tribes of British Central Africa, as we have mentioned, it may be a premarital requirement, marriage being postponed until puberty. Among the Akamba in British East Africa a girl is not thought desirable in marriage until she has conceived (Eliot, C. N. E., *The East Africa Protectorate*, p. 125).

Infant betrothal, sometimes confused with child marriage, often serves actually to tabu premature intercourse. In the Admiralty Islands in northwestern Melanesia the betrothed girl, often very young, must cover herself with mats in any encounter with any male of the whole kin group of her fiancé. Among the Yoruba of west Africa (Ellis, A. B., *The Yoruba-Speaking Peoples of the Slave Coast of West Africa*, p. 154) the virginity of the bride is of importance only if she has been betrothed in childhood, in which case tokens of virginity must be produced even though the marriage does not take place until she is adolescent. Among the Ibibios of southern Nigeria (Talbot, D. A., *Women's Mysteries of a Primitive People*, p. 88) the distinction between infant marriage and prepubertal sex relations is even more pronounced. While infant marriage is not uncommon, and the bride is taken to her husband's home, intercourse before her maturity is forbidden, and if its occurrence is proved the family can claim her back without returning the dowry.

It is often very difficult to determine from the available material the relation of child marriage to prepubertal sex relations. In Australia, for instance, child betrothal is universal and the mother of a wife to be is called mother-in-law even before the birth of the promised child who will later be the bride; similar forms of address are employed toward all her kin group. Prepubertal sex relations, however, are rarely mentioned. Spencer and Gillen (*The Native Tribes of Central Australia*, p. 92) give the age of consummation of marriage at between fourteen and fifteen, but Malinowski (*The Family among Australian Aborigines*, p. 257) concludes after a survey of all the material that the usual age is between ten and twelve.

India is of course the country where child marriage is most striking. Child betrothal is here universal with the exception of some native tribes least touched by Hindu influence. According to

the religious code it is a sin on the part of the father if his daughter is not married in childhood. There is, however, a wide range in the date of consummation of marriage. In the western provinces especially it is essential that there be two ceremonies separated by an interval of from three to eleven years as determined by the girl's parents. The custom of early consummation of marriage is most widespread in the eastern provinces, particularly in Bengal, where the canonical rites of Hindu marriage require girls of the highest castes to commence married life at nine years of age.

In India, as is generally true of primitive peoples also, the problem of pre-adolescent establishment of an independent home does not arise. The husband is customarily a mature member of the community, and the child bride is taken into his household without her being assigned any serious responsibilities. As we have seen, even in cases of early marriage between age mates in primitive tribes the responsibilities of the married couple are not materially changed because of their relation to the larger house group.

In western civilization, on the other hand, marriage means setting up an independent family. In order to assume the economic burden of a family the husband must be master of some trade or at least able to qualify for a job in competition with men. The complexity of modern civilization has therefore made child marriage a special social liability. But this is a problem rising out of special social conditions and special traditions as to what is involved in marriage, as we imply in every discussion of the different ages that constitute "early marriage" in different economic classes of our own society.

If in connection with the establishment of a home child marriage is a social matter having different implications according to the customs and conditions with which it is associated, this is equally true in its relation to the status of women in any society. Women may have high status in societies in which infant betrothal and prepubertal intercourse are practised; on the other hand, adult marriage may be the rule where women have exceptionally low status. There is no necessary connection. In tribes as far apart as the Iroquois and the Masai of east Africa marriage did not take place until both parties were about thirty years of age. This, however, was not indicative of the high status of woman since her position was high among the Iroquois and low

among the Masai. Although marriage was in both cases postponed because of its incompatibility with warfare, the idea was differently developed in the two regions. Among the Iroquois relations with a woman weakened a man's war magic and were therefore eschewed by warriors. Among the Masai it was the responsibilities of a householder that were avoided, and until a man had passed the age from which warriors were recruited he lived in a bachelors' kraal and had free access to the kraal of the unmarried women.

Only in our own civilization has this connection between postponement of marriage and the improvement of the status of women been emphasized. As with other aspects of child marriage, this one is a function not of prepubertal marriage or even of "early" marriage per se, but of special social conditions which in their totality in a special culture have made the association inevitable.

RUTH BENEDICT

United States. In the United States the term child marriage refers usually to marriages in which one or both of the participants are under the age of sixteen, and according to available statistics applies almost entirely to girls. Such statistics are for the most part incomplete due to falsification in order to evade legal age minima. The census of 1920 recorded 12,834 married girls of fifteen years of age and 5554 below that age. There were also 825 widowed or divorced girls fifteen years of age or younger.

Child marriage occurs more frequently in rural than in urban regions and is particularly conspicuous in isolated sections such as are found in the southern Appalachian mountains. It is most common, however, among Negro girls and among those of foreign birth, especially Italian. Many of the native white girls who figure in child marriage statistics are mentally deficient or delinquent, but many others are of apparently normal equipment, sometimes belonging to families of established, middle class background. Their marriages are often hastily contracted, usually without parental consent. Some parents, however, consent to child marriage because sex relations have taken place; in such cases some insist upon marriage under threat of criminal action against the boy or man concerned.

A scientific study of the outcome of child marriages would present many difficulties and has never been attempted. But social workers

have recorded so many cases in which the marriage of young girls has been marked by general domestic discord often ending in annulment, divorce, desertion or separation that a presumption is created against the practise. Such medical or biological testimony as is available indicates that as a rule maternity imposes a physical strain upon girls under sixteen which they are not fitted to bear. Nor are they better qualified for the difficult task of caring for children in an advanced civilization. Statistical evidence on these points is inferential, for in existing studies separate figures for mothers under sixteen years of age are meager and thus far unanalyzed, but extremely youthful motherhood seems to be unfavorable to survival both of the mother and of the child. Similar conclusions regarding infant mortality were reached from a study of the 1911 census of England and Wales, some evidence being offered, however, that such a situation was due rather to the inexperience of very young mothers than to any physical causes.

On January 1, 1928, in twelve states there were laws permitting twelve-year old girls to marry, provided their parents consented. In ten states and the District of Columbia the minimum age was fourteen years, in seven it was fifteen, in eighteen it was sixteen and in New Hampshire alone it was eighteen. Where the legal minimum age is highest exceptions are usually allowed, the most frequent reason for such discrimination being expectancy of motherhood. The law prevailing in most states that girls unless gainfully employed must attend school until the age of sixteen is generally not enforced in cases of married girls. Falsification undermines the enforcement of legal age requirements and a few marriage license issuers have demanded evidence more reliable than the affidavits of contracting parties. In 1927 New York state created a preference by requiring documentary evidence of age from all applicants for marriage licenses who seem to be less than twenty-one.

FRED S. HALL

DEPENDENT CHILDREN. The term dependent child is commonly applied to a child who is dependent upon others than his own parents. A distinction is made in both legal status and common usage between neglected children, whose parents treat them cruelly or deprive them of adequate care, and dependent children, who have lost either one or both parents or whose parents are unable to provide them with

the necessary minimum of food, clothing and shelter.

With rare exceptions the social problem of child dependency is linked with that of poverty. In many cases the causes are more immediate and direct: the death of parents, the breaking up of homes by desertion, separation or divorce, the imprisonment of the father or the inability of the unmarried mother to support her child. In many of these instances slipshod management, undesirable living conditions, drunkenness and the physical and mental incapacity of parents to care for children are more dominant factors than the economic status of the family. In others child dependency is directly caused by poverty resulting from such factors as unemployment, sickness or low earning power. The various types of social insurance in effect in many European countries and to a lesser extent such measures as workmen's compensation insurance in the United States help to regularize the family income and hence to keep children from becoming dependent. In general, every improvement in the social and economic status of the great masses of population has its reverberations in the extent and type of child dependency. Activities designed to maintain the home and advances in the field of child care are preventives. As war is one of the chief causes for child dependency on a large scale, all efforts designed to restrict it have a direct effect on the problem.

Such broad programs aim at the removal of the causes of child dependency. Where child dependency presents itself for immediate adjustment, however, temporary or in some cases permanent substitutes for parental care must be planned.

The most common form of supplementary care for dependent children in their own homes is the allowance given to mothers through state or national aid. Organizations for children's aid and family case work also contribute, though in extremely small proportions, to the support of dependent children in their homes. Temporary or permanent care may be given in an institution or in a private home; the latter may be either a free or a boarding home. Costs of such care are borne sometimes by public funds, sometimes by private charities or by both. In the United States the institutions are usually of a sectarian character; approximately one tenth are under public auspices.

Among the various peoples recognition of the problem of dependent children and the concept

of the minimum provisions necessary to them have varied widely from time to time. For any but nomad peoples there can be only two substitutes for parental care—some other family home, corresponding with what we now call the foster home, or some larger group, the institution. The records of ancient civilizations show little organized effort along these lines. Provisions for adoption in the Hammurabic code were evidently framed more for the protection of the new parent than of the child. In Greece and Rome there undoubtedly existed individual adoption in cases where the parents had died, as well as in cases where children were rescued from the widespread practise of infant exposure. In Athens some provision was made for children whose fathers had fallen in battle. In contrast, the conscious Jewish tradition of providing for dependent children dates back to several centuries B.C. The synagogue was, and to a great extent still is, for the Jew, the center not only of religious but of social and philanthropic activities. These activities include support of the poor, education of their children and community responsibility for orphans. Many of the communal customs regarding marriage had as their basis the preservation of the family unit.

The spirit of regard for the dependent child, implicit in many passages of the Old Testament and the Talmud, was confirmed and reinforced in the teachings of Jesus. The definition of religion in the *Epistle of James* includes the duty of visiting the fatherless and the widowed. As the early Christians formed congregations they seem to have added to their individual efforts the simply organized help of deacons, who distributed collections from members of the congregation to those in need. This help also included the payment to widows of a sum of money to enable them to care for their children at home and the device of paying widows to care for orphans. In some instances two or more widows were paid to come together in a larger dwelling and to take several orphans for care. These practises may be taken as the precursors of the mother's pension, of the system of boarding out and of the institution for dependent children. During the following centuries small groups under the influence of church and synagogue, however mistaken their methods may have been, constituted persistent germinal units for organized care of dependent children. During the Middle Ages there developed throughout most of western Europe various extra-parish forms of care. These included the establishment of

hospitals and provision for the care of dependent children in monasteries, orphan asylums and foundling hospitals.

So long as the feudal unit of economic and civil life prevailed in western Europe the status of an individual in the self-sufficing manorial community was such as to give the dependent child some recognized right to support within the economic group. Where the church parish coincided in area with the manor, as it often did, church charity could all the more easily furnish what support the child lacked under the custom of the particular manor.

When the self-sufficing feudal life in England began to disintegrate, after the middle of the fourteenth century, the individual no longer had a claim upon the manorial group. The number of wandering, begging and destitute persons had become so great by the time of Elizabeth that the previous statutes culminated in the 43rd Statute of Elizabeth in 1601. In this statute England recognized for the first time the duty of the political or civil state to make some provision out of taxes for the care of all persons, including children, whom family care, church charity or private generosity still left destitute.

This statute provided for the earliest variety of foster family care for dependent children through the simple adaptation of the indenture foster home of the guilds, already used by parents who wanted their children to become artisans. Such apprenticeship and indenturing was under the direction of justices of the peace of the English parish. By this device the dependent child, if not too young, could begin to pay at once for his own keep and before the end of his indenture period, at the age of from eighteen to twenty-four, could also pay back the principal and compound interest on any deficit incurred by his employer.
